POWER HOUSE

A monthly newspaper devoted to the Generation, Transmission and Application of Steam, Gas, Electric, Air and Water Power; and to the operation of Refrigerating Machinery.

Published by The MacLean Publishing Company, Limited, 143-153 University Ave., Toronto

MONTREAL: Southam Bldg. LONDON, ENG.: 88 Fleet St., E.C. WINNIPEG: 1207 Union Trust Bldg.

Vol XI—No. 1 Publication Office, Toronto—January, 1918 Published Monthly $1.00 per Year.

30999

It's the first rule in good valve buying

Look for the Diamond Trade Mark!

JENKINS BROS.' VALVES

Have a Host of Imitators

It pays to insist upon getting the genuine. Because it is only with genuine Jenkins Bros.' Valves that you are sure of the service which has given these valves their reputation. The *appearance* of Jenkins Bros.' Valves can be copied, but the *service* goes only with the original.

There's a Jenkins Bros.' Valve for every service

Look for the Diamond Trade Mark before buying

Jenkins Bros.' Valves are approved for use in Ontario and the Western Provinces by the Departments of Public Works.

Catalogue No. 8 free on request.

For Better Service in Mechanical Rubber Goods

THE United States Rubber Company, on January 1st, 1918, inaugurates an improved method of marketing in its *Mechanical Goods Division.*

This division includes Rubber Belting, Packing, Fire, Steam, Water, Garden and all other kinds of hose; Rubber Tiling, Mats, Matting, Jar Rings, Toys, Plumbers Supplies; Rubber Tape, Soles, Heels; Fibre Soles and hundreds of other rubber items.

Heretofore these goods have been marketed through subsidiary companies that for years have served all classes of industries, railroads, etc. These subsidiaries include:

Revere Rubber Co.
Peerless Rubber Mfg. Co.
Mechanical Rubber Co., Cleveland
Mechanical Rubber Co., Chicago
Sawyer Belting Co.
India Rubber Co.
Eureka Fire Hose Mfg. Co.

This plan will centralize the distribution of all these companies in one organization having branches and agents all over the country. This means quicker and better service everywhere for users of mechanical rubber goods.

The subsidiaries will continue to manufacture the brands, such as

Rainbow Packing, Four Ace Belting, Giant Hose, Etc., Etc.

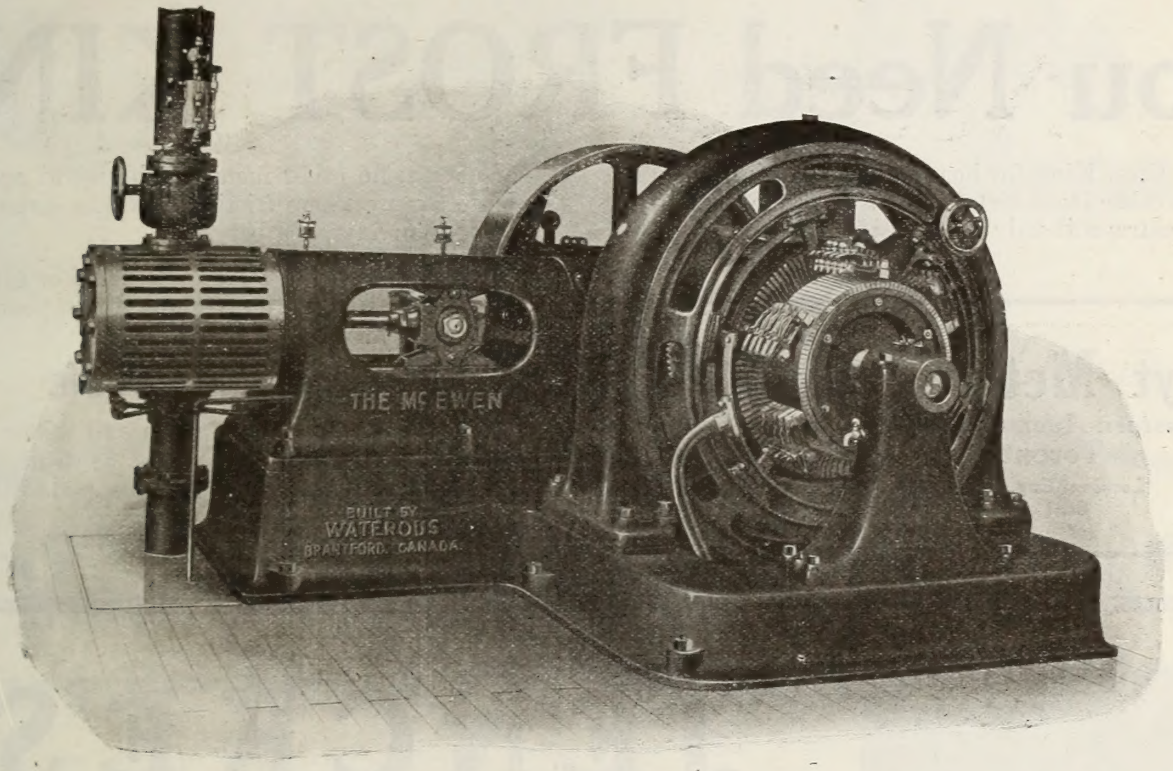
for which they are famous. The same high standard of quality and workmanship will be maintained. In addition the great seal of the United States Rubber Company, the hall mark of quality and value in rubber goods will identify these goods.

The assembling of all these well known brands in one selling organization makes the most complete line of mechanical rubber goods in the world. With distributors everywhere and factories in the large centers east and west we assure our customers the maximum in service and quality.

United States Rubber Company

HIGH SPEED AUTOMATIC

McEwen Engines



SIMPLICITY of operation, economy in steam combustion and the ability to stand up under hard usage—are features that make the McEwen Engine ideal for Isolated Plant Installation.

Both Simple and Compound types are built. Sizes range from 40 to 700 H.P. Every McEwen Engine is Canadian built throughout. It is tested and inspected before leaving the works and is backed up by a rock-bottom regulation guarantee.

Waterous Isolated Plant Equipment

McEwen Automatic Engines.
Waterous Boilers—any style.
Feed Water Heaters.
Injectors.
Steam Separators.
Circulating Pumps.
Feed Pumps.
Exhaust Heads.

You say, "Money Talks." Well, it does. $5,000,000, the combined annual sales of Hoyt Babbitt Metals, talk Hoyt quality.

You Need FROST KING

You need Frost King for heavy duty and high speed work. No other Hoyt Metal is so lastingly good when service is extraordinarily severe—and that is saying, of course, no other metal in the world equals Frost King for use where friction would be serious without a superlatively good babbitt.

Frost King is the greatest anti-friction general purpose Babbitt we've compounded in 40 years of scientific metal mixing.

NICKEL GENUINE

is the Hoyt Metal for dynamo and motor. It is an extremely high copper alloy; as near an actual bronze, in fact, as a babbitt can be made with success.

Write for Hoyt's Catalog.

JENCKES BOILERS

Vertical Tubular
Horizontal Tubular
Locomotive Types
Heating Boilers

All sizes to any Provincial Act

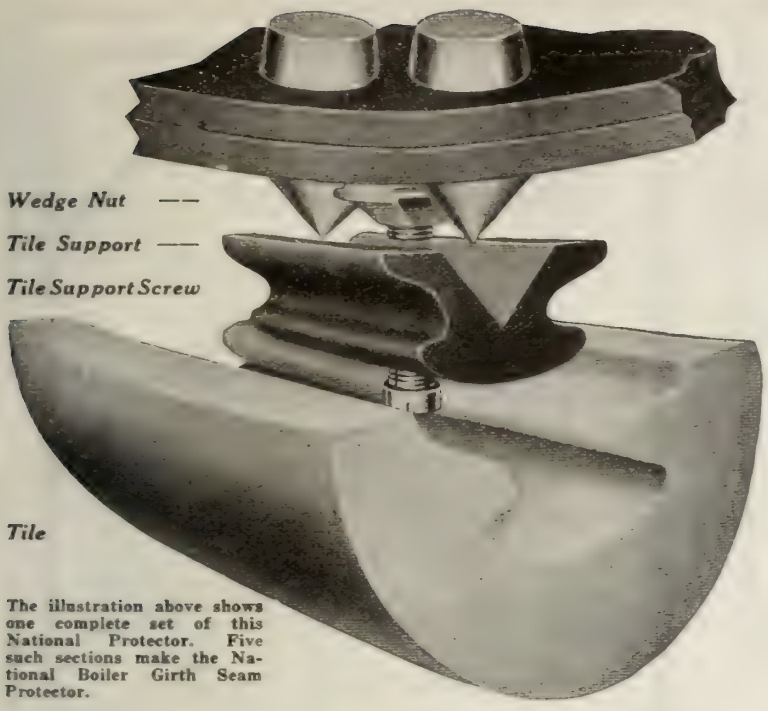
are built at the Jenckes Works, where facilities are uncommonly good for building good boilers.

They are built by men who have given many years to boiler-building work.

They pass a rigid test and inspection under high pressure before they are shipped.

A well-assorted stock of finished boilers and boilers in course of construction is on hand. **Write:**

The Jenckes Machine Company, Limited
Sherbrooke, Montreal, St. Catharines, Toronto, Cobalt, South Porcupine, Vancouver
Works: SHERBROOKE, QUE. ST. CATHARINES, ONT.



The illustration above shows one complete set of this National Protector. Five such sections make the National Boiler Girth Seam Protector.

National Boiler Girth Seam Protector

Ends Boiler Repairs

Is Your Boiler Leaking Profits? Because Fire-Cracked at the Seam.

Do not rush your boiler to scrap value by neglecting to remedy at once and permanently the fire-cracked, leaking seam just above the fire-brick arch.

If yours is a new boiler, then do not delay until crystallization and fire-cracks appear.

Permanently remedy the old fire-cracked seam, positively protect the new, by having your fireman caulk up the girth seam and attach the National Boiler Gi th Seam Protector.

In 30 minutes your own fireman can easily do the work, so simply constructed is this durable, service-proven Protector.

Frequent "patching up" is a costly waste of time and labor. Neglect lowers your boiler's efficiency and shortens its life. Profit by

What Users Say

Unstinted is their praise of this National Girth Seam Protector. Their letters sent us with second and third orders we have on file, and we can show you copies or the originals.

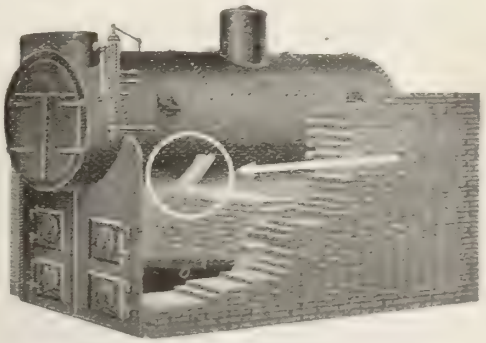
A few satisfied Canadian users of **The National Girth Seam Protector** to whom we invite you to write—

Toronto Paper Mills, Cornwall, Ont.
Dominion Iron & Steel Co., Ltd., Sydney, Nova Scotia.
Dominion Products Co., Ltd., (National Plant, Montreal).
Montreal Locomotives, Ltd., Longue Pointe, Que.
Howard Smith Paper Mills, Beauharnois, Que.
Montreal Cotton Mills, Valleyfield, Que.

Indorsed by Boiler Engineers, Boiler Inspectors and Insurance Companies, you have in this National Protector the only perfected device that will prolong the life of your boiler by keeping the girth seam absolutely dry.

Booklet, explains all details—the cause of fire—cracked boilers, how to prevent and how to lastingly remedy.

Send to-day for your copy.



MADE IN CANADA

NO SMOKE

The JONES
Underfeed Automatic
STOKER

Automatically lowers your coal bill 15 to 25 per cent. It feeds the coal scientifically—neither too much nor too little - precisely enough to keep steam pressure steady regardless of load. Under YOUR boilers the Jones Stoker means

More Steam from Less Coal —and
CHEAPER COAL

The Jones eliminates smoke nuisance and money loss in wasted fuel. It does away with much coal-shoveling labor and a lot of fire worry, too.

We've a booklet illustrating Jones Underfeed Automatic Stokers in Canadian plants. It also explains how the Jones Stoker ordinarily pays for itself. Write:

Jones Underfeed Stoker Co.
LIMITED
37-41 Britain Street, TORONTO

Boiler House Elevators

YOU cannot get our new catalogue on Boiler House Elevators unless you ask for it in writing. This is necessary under the new regulations, but we shall be very pleased to send it to you on request. It is well printed and profusely illustrated. Secure your copy now.

Economy Renewable Fuses Save 80%

Anyone Can Renew a Blown Economy Fuse

It takes but a moment to have the blown fuse back in the circuit every whit as good as new with the aid of an Economy "Drop Out" Renewal Link.
Used in the world's greatest plants and institutions—thousands upon thousands annually—because there isn't a better fuse at any price and there isn't another fuse that will actually lessen your fuse bill 80% or more.
Made in Canada. Sanctioned by the Canadian Fire Underwriters' Association.

Murphy AUTOMATIC Furnace

PAPER MILLS

Paper mill power plants are operated 24 hours per day and 365 days per year—less 12 hours per week; high duty conditions!

That MURPHY STOKERS "make good" for requirements is evidenced by 11 *repeat orders* in 1917, for 25 *stokers*—8,700 H.P and *"first orders"* from six mills, for 22 *Murphys*—5,400 H.P.; 47 stokers, 14,100 H.P.

The first Murphy installation in a paper mill was 34 *years* ago; that mill has ALWAYS BEEN USING Murphy Stokers.

For printed matter address,

ICE MACHINERY SUPERIOR SINCE 1862

Canadian Representatives:
FRICK ICE & REFRIGERATING COMPANY, Montreal, Canada

Lost--134 Tons of Ice Per Year

268 tons of refrigeration—approximately 134 tons of ice per year—that is the loss which results from a 1½-inch uncovered brine line, 200 feet long, with the atmosphere at 75° and the brine at 15°. Think of it—this loss is equivalent to 2½ days' output of a 100-ton refrigerating plant! Figured in terms of ice, the loss is equal to a solid block of ice 10 feet wide, 15 feet long and 30 feet high, or in other words, 1,342 two hundred-pound cakes. Exposing brine or ammonia lines to the atmosphere is just as illogical as storing ice in the sun.

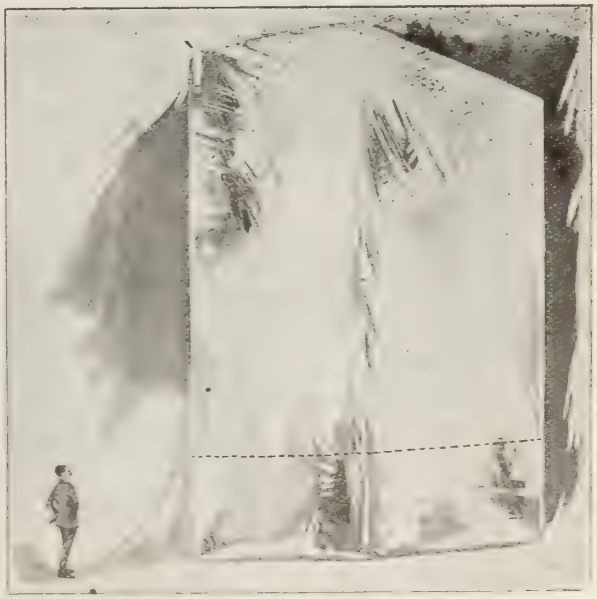
Nearly four-fifths of this loss can be saved by using the correct thickness of

Nonpareil Cork Covering

For Cold Pipes and Tanks

In fact, under ordinary conditions, Nonpareil Cork Covering will save its own cost the first year and continue to yield big dividends for a long time to come. Cork is one of the best known nonconductors of heat and its very nature adapts it to the requirements of insulation for cold pipes better than any other material. Nonpareil Cork Covering is durable in service, easy to apply, neat in appearance and reasonable in cost.

Our 64-page illustrated book, "Nonpareil Cork Covering," will be sent, free of charge, upon request.



pro luce a cake of ice 10 x 15 x 30 feet high, weighing 134 tons. Nonpareil Cork Covering will save the
or 110 tons.

TORONTO JANUARY 1918

The Economy of Business Paper Advertising

By H. E. CLELAND, NEW YORK

Awarded the Higham prize at the convention of Associated Advertising Clubs, at St. Louis, June, 1917
This prize is given annually to the one delivering the most constructive address in fewest words.

(Continued from last month)

SO, in a quiet, substantial, and most-times unheralded way, the business papers are leaders of progress in their respective industries and in this character they tie to them the progressive men of the industries. Only progressive men are worth while to advertisers. Therefore, the business papers not only aim directly at those industries where the advertisers' products may be sold, but they automatically select the men in each industry whose words carry weight of buying authority. But modern business papers—those which, for instance, are members of the Associated Business Press—go even further and put before the advertiser the exact number of each classification of subscribers. So that, in a technical industry, for instance, the advertisers are shown how many firms, executive officers, purchasing agents, superintendents, engineers, etc., are on the paid subscription list and from these the advertiser may estimate the buying power which each publication holds for his product.

In other words, the business papers are helping to put advertising closer to the status of an exact science.

And that, in turn, spells greater economy in advertising.

"BUYING POWER" THE TEST.

I said that the buying power per subscription in a business paper was greater than the buying power per subscription of any other medium because things are bought for business and not private consumption.

To illustrate this, one industry last year bought approximately $500,000,000 worth of goods and 90 per cent. of this industry is covered by two business papers having a total paid circulation of 22,000, or an average of material bought per subscriber of about $20,500.

Since it is a fact that less than five per cent. of our population has an income of over $4,000 per year, it may readily be seen that private and business consumption are far, far apart.

I quote from an industry with which I am familiar and not one picked because of its exceptional buying capacity. There are probably many which exceed it.

So, the thought is that each dollar invested in business paper advertising buys more potential sales results because each appeals to a greater buying power.

And that, too, is economy in advertising.

THE POTENT THING.

Now, all of you advertising men know that the really potent thing in advertising is cumulative effect. You know that even poor and mediocre advertising, persisted in, pays and pays handsomely.

You know, on the other hand, that sporadic advertising, even of the best kind, has only a temporary effect and that effect is seldom of sufficient force to pay.

The splurger makes his splash, the ripples die out and the surface becomes calm and serene. He loses because his advertising is too costly to be kept up continuously.

THERE IS NO SUBSTITUTE FOR CONTINUITY IN ADVERTISING.

It is possible, because of the low rates in business papers, for practically any manufacturer to advertise week in and week out or month in and month out, to hammer away until by sheer force of persistence he drives his claims home and sells his prospect.

It takes time to sway men the advertiser's way. It takes repeated effort to get the first return from advertising.

The advertising catacombs are filled too full of the bones of half-tried efforts.

There are publishers who permit and agents who induce advertisers to adopt "splurge" advertising, and these I charge with the crime of high treason against the cause of effective advertising.

Advertising which cannot reap the benefits of cumulative effect is not as profitable as it ought to be. Therefore, it is not as economical as it might be.

Business paper advertising is economical because, intensive circulation permits rates low enough to allow practically any manufacturer to advertise continuously.

FOLLOW THE SALESMAN'S METHODS.

That advertising is best which comes closest to the best in salesmanship.

What does the salesman do? Assume that he is selling steam engines, does he make a house-to-house canvass of say, Chicago? Not on your life. Aside from the utter insanity of that procedure, it takes twelve years and eight months for one man to make a house-to-house canvass of Chicago. He picks out steam power plants or plants in course of design or of building and goes to those and no others.

Does he make his sales talk to the office boys and stenographers in those plants? Not in one thousand years. He goes to the man who buys or recommends.

Does he talk to these men about steam calliopes or about steam engines You know the answer.

Does he endeavor to show the economy and efficiency of the steam engine as a prime mover and does his talk resemble that of an engineer or a chauffeur? You know the answers to that, too.

Now, why does the salesman do these things? Because the efficient salesman knows how to follow the straight line—the shortest distance between two points—and because his concern will not pay for the super-expense of roundabout methods.

For precisely the same reason, the wise manufacturer uses the business papers to carry his advertising message.

Steam-Electric Plant
Dominion Power & Transmission Company.
Hamilton, Ontario.

Staff Article

The power house plant, machinery and equipment described in the following article represent a degree of excellence in design and arrangement equalled by few plants elsewhere and possibly excelled by none. In addition to being evidence of the technical skill and ability of the officials concerned with its construction, it further affords convincing evidence of the manner in which reputable power companies realize both their duty to present consumers and the necessity of preparedness for emergencies as well as future developments.

THE tremendous war-created activity in metal working and power using plants throughout Ontario, with its resulting drain upon the electrical resources of the province, has directed so much of the general public's attention to hydro-electric power plants and schemes that comparatively little attention has been given to the scale on which privately-owned systems have been increasing their capacity and strengthening their system generally so as to insure continuity of service under any required circumstances.

Location and Capacity

These circumstances render more than ordinarily interesting the extremely modern and complete steam operated power station which has just been recently completed and put into service by the Dominion Power & Transmission Co., Hamilton, Ont. The plant is situated just outside the eastern limits of the City of Hamilton, and is designed to have an ultimate capacity of 75.000 K.V.A., of which 25,000 has been installed up to the present time. The output is delivered at a voltage of 42,000 to the high tension lines of the company, whose main source of supply is their hydraulic power plant at DeCew Falls, 34 miles distant from Hamilton.

In addition to its generating capacity, the steam plant is designed to act as a stepdown transformer station of 25,000 K.V.A. capacity to transform the high tension current to 13.200 volts for distribution to local factories in the manufacturing district in the near vicinity. Fifty per cent. of this stepdown capacity, i.e., 12,500 K.V.A., has been installed so far.

General Layout

A cross sectional elevation of the entire plant is shown in Fig. 1, and an exterior view of the building from the same viewpoint forms the title illustration. By comparing the location of the principal features a clear idea of the arrangement and disposition of the various equipment, items and departments will be obtained. Fig. 1 is particularly interesting, as the actual arrangement of the plant as shown enables the process of power generation to be followed in strict sequence of operation.

Coal Handling

Commencing at the right, the coal handling plant is shown where the fuel is dumped direct from the cars into the hopper of the coal crusher or placed in auxiliary storage provided in this building, which has 1,250 tons capacity. The coal handling plant, which was supplied by C. O. Bartlett & Snow Co., has a capacity of 60 tons per hour, and includes a feeder, crusher, elevator and weighing larry. The steel-cased double-plunger feeder has a 26 in. by 30 in. opening, the coal being moved by two plungers operated by adjustable eccentrics. It is driven by sprocket and chain drive from crusher countershaft through a clutch, so that it can be cut out at any time and the crusher driven independently.

The feeder discharge is coupled directly to the top of a 2-roll crusher, directly gear-driven by a 25 horse-power Westinghouse motor at 750 revs. per min. Each roll consists of two heavy cast iron spiders supporting six cast steel segments, forming a roll 26 in. dia. by 24 in. long. The roll shafts are 4 7/16 in. dia., one being rigidly supported, while the other is carried on adjustable sliding bearings backed up by heavy coil springs. They are set to deliver coal of 2 in. size and under.

The bucket type elevator is a conspicuous feature in Fig. 1, extending from the crusher below the train tracks up to the bunker between the stacks. It has a length of 138 ft., and is enclosed in a casing 5 ft. high by 9 ft. wide, with ladders on either side. The coal bunker has a capacity of 420 tons, and is pro-

vided with three 18 in. by 18 in. double undercut doors, through which it drops into the weighing larry.

Boiler Room

Interior view of boiler room, Fig. 2, shows the weighing larry in position for supplying fuel to the two nearest boilers. The hopper of the larry has a capacity of 5 tons, and as can be seen in the illustration, is supported on two cross girders like an overhead crane, the rail centres of the overhead track being 21 ft. The hopper scale has a capacity of 10 tons, with reverse reading beam. The gates on the delivery spouts which lead from the hopper to the stokers are controlled from the larry cage, as are also the overhead bunker doors. A 5 horse-power Westinghouse slip-ring polyphase motor is direct geared to the larry trucks for traversing purposes.

FIG. 2. MAIN AISLE OF BOILER ROOM, SHOWING OVERHEAD COAL LARRY WHICH WEIGHS THE FUEL AND DISTRIBUTES THROUGH CHUTES INTO THE STOKER HOPPERS.

Inclined Tube Boilers

Four water tube boilers of the inclined tube type are installed. These are built in single settings, and were supplied by the Edge Moor Iron Co., having an individual capacity of 1,050 horsepower. Each boiler has four drums made of 7/16 in. plate, with an outside diameter of 35⅛ in. and a length of 20 ft. They are constructed of fire box steel, and the longitudinal seams are double butt strapped and triple riveted.

Each boiler has 472 Am. standard soft steel tubes, 4 in. dia. by 20 ft. long, the two lower rows being No. 9 gauge and the balance No. 10. Flanged steel header construction is used, along with oval hand holes and inside covers, which are tightened by boiler pressure, and are independently removable.

Stoker Installation

The mechanical stokers were constructed by the Taylor Stoker Co., and each has 11 retorts, the total width being 19 ft. 6 in. and depth 8 ft. 3½ in. One stoker engine is provided for each pair of stokers, and the same practice is followed with the fan equipment. The fan engines were built by the Harrisburg Foundry & Machine Works, and are of horizontal type. They are located on the ground floor level next the condensers, and are supplied with heated air from the generator cooling system.

The fan wheels are direct connected to the engine crankshafts and are capable of delivering sufficient air to operate all of the stokers at 150 per cent. of their normal rating. The stokers, individually, are capable of firing their respective boilers at a sufficient rate to force them to 235 per cent. normal rating without difficulty. Boiler accessory equipment includes Ashton pop safety valves; Hancock feed water and check valves; Faver blow-off valves; Homestead blow-off cocks; Ashcroft steam gauge and Reliance water column. Automatic soot blowers and the customary instruments to enable the engineers to operate the boilers efficiently are likewise provided. Rolling doors provide convenient access to the tube header and form an attractive front to the boiler.

Foster superheaters are installed on each boiler, under guarantee to raise the temperature of 31,500 lbs. of steam per hour to 538 degs. F. which, at a pressure of 200 lbs. per sq. in. represents a superheat of 150 deg. When operating at 150 per cent. of boiler rating, this degree of superheat would be increased to 160.

Chimney Stacks

Flue gases are distributed to the atmosphere by two chimneys of radial brick construction, erected by Canadian Kellog Co. The stacks are of identical proportions, being 240 ft. high above foundation; 22 ft. 2 in. dia. base; 12 ft. internal top diameter. They are lined to a height of 40 ft. from a point 2 ft. below flue opening. The lightning conductors have 6 copper points, ¾ in. dia. by 8 ft. long with 1½ in. solid platinum tips all connected and grounded in accordance with best modern practice. Accessory equipment includes 4 in. H. and M. draft gauges and connections and 2 in. pyrometer connections.

Water Purification Plant

The make up water for the plant is obtained from Burlington Bay and in order to render it suitable for use is

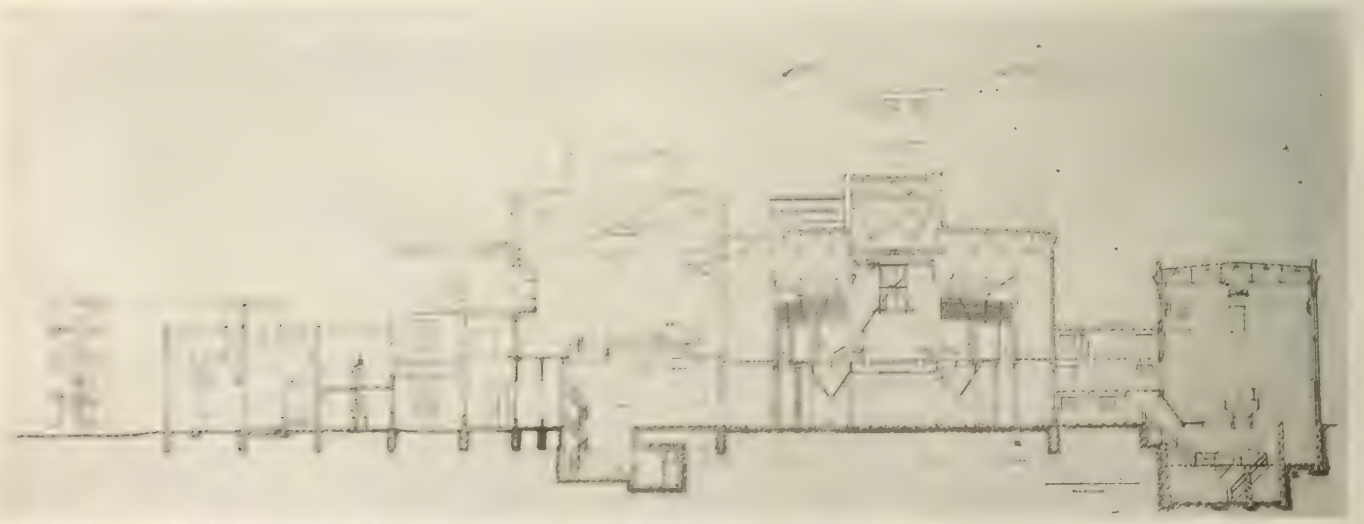

FIG. 1. SECTION OF POWER STATION. NOTE SYSTEMATIC ARRANGEMENT OF OPERATIONS FROM RECEIPT OF FUEL AT RIGHT TO DELIVERY OF CURRENT TO DISTRIBUTING LINE AT LEFT.

treated by the We-Fu-Go system of water purification. This plant is housed in a separate building at the extreme left of the title illustration, and was installed by Wm. B. Scaife & Sons Co. It is of quite extensive proportions, and amongst principal items are two reaction ft. 4 in. high, equipped with mechanical 4 in. high, equipped with mechanical stirring devices and each requiring 4 hours for treatment of its capacity of water.

Two filter tanks 8 ft. dia. by 5 ft. 4 in. high contain the filter beds of crushed quartz (98 per cent. silica) supported by a layer of washed and graded gravel. The flow of water from the settling tank into the filter tank is regulated by brass-fitted balanced valves with seamless copper floats. Constant alarm bells operated by the floats ring in water softener and boiler rooms. The filter beds are provided with air wash pipes for cleansing purposes, having discharge openings equally distributed over the filter beds and connected to a pressure blower.

The two generating units installed are identical in type and size, being Westinghouse turbo-generators of 10,000 equivalent K.W. capacity, delivering 3-phase current at 6,600 volts; 1,100 amps. per terminal; 66 2-3 cycles. The generators are of the 4 pole type and run at 2,000 revs. per min.

The layout of the plant is such that when future extensions are completed, six turbo-alternator units will be accommodated, each of a maximum rated capacity of 12,500 K.V.A. giving a total station capacity of 75,000 K.V.A. or an equivalent of 60,000 K.W. at a power factor of 80 per cent.

The generator department occupies the central portion of the power house, the three principal parts—boiler room, generator department and switch and transformer rooms being parallel with each other, as shown in Fig. 1. There are three floor levels in the generator department; the lowest one is below ground level and forms the pump well for the condensed circulating pumps; the ground level floor on which are carried the condensers and auxiliary equipment, and on which rest the foundations for the turbo-generators; the main or operating floor on which the generating units are erected, and which is level with the boiler room floor (see Fig. 1). Two views of the main floor are shown in engravings Figs. 3 and 4 while a view of the auxiliary equipment for one unit is shown in Fig. 5. The plan layout of the entire generating equipment is shown in diagram Fig. 6.

Steam Turbines

The design of turbine adopted is that known as the "impulse reaction" type. The turbines are of Westinghouse construction and employ multiple expansion parallel flow.

Steam is admitted through primary admission valves of balanced poppet type enclosed in steam chest. Secondary admission valves, automatically operated by mechanical connection with governor, are arranged to admit steam to lower stage when load exceeds capacity of turbine with steam received through primary valve. The secondary valve will also operate in this manner should vacuum or steam pressure fall to a point where the turbine is unable to carry the load normally, returning to its seat when excess capacity is no longer required.

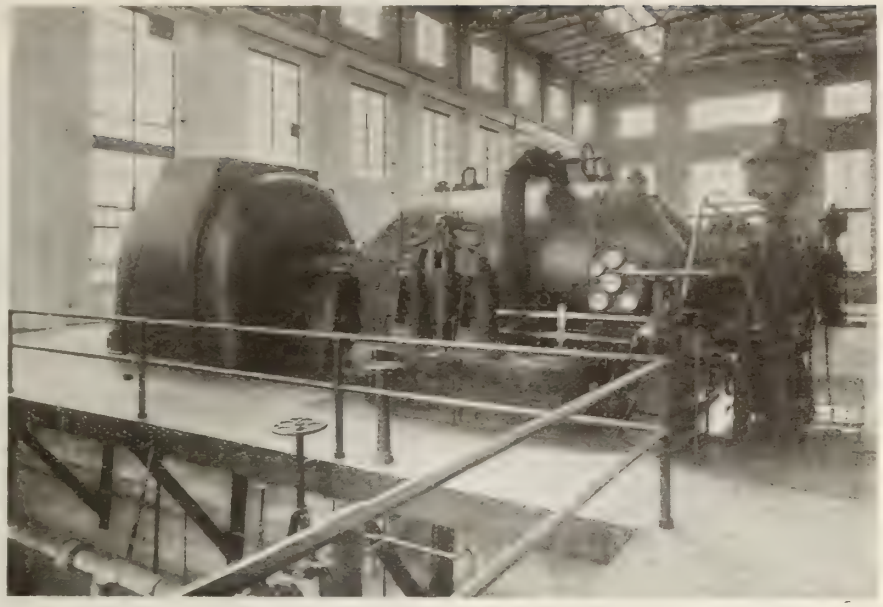

FIG. 4. ONE OF THE 12,500 K.V.A. TURBO-GENERATOR UNITS, SHOWING STEAM ADMISSION VALVES, GOVERNOR GEAR AND THROTTLE VALVE.

An automatic throttle valve, controlled by separate safety governor, is arranged to close before the turbine speed exceeds a safe limit. It can be adjusted for any predetermined speed, and means is provided for tripping by hand from a convenient location.

Blading

The impulse section consists of two rows of moving and one row of stationary blades, the balance of the machine consisting of reaction type blades. The steam passes through the impulse section towards the generator; and then towards the centre of the turbine where it divides and passes toward each end in opposite parallel flows. Nickel iron is the material of which the impulse blades are constructed, and phosphor bronze for the reaction blades.

The main bearings are self-aligning, and lubrication is effected by an oil pump operated from worm gear on turbine shaft, with delivery and return piping between reservoir and bearings, sufficient head being provided to insure ample flooding of bearings.

A speed variation of between 3 and 4 per cent. can be obtained under normal conditions, while a speed changing device is provided with remote control from the operating station.

FIG 3. MAIN FLOOR OF GENERATOR DEPARTMENT. NOTE EXCITER SET IN FOREGROUND, ALSO EXHAUST AND CIRCULATING WATER PIPES.

Condensing Plant

The circulating pumps in the pump well are turbine-driven centrifugals of the closed impeller type. The location of the pump is such that the intake level is 1 ft. below discharge level, the total pumping head, exclusive of friction head through condenser, being 2 ft. The pumps are gear-driven by Westinghouse impulse turbines through reduction gear of the Westinghouse self-aligning type, having right and left hand helical gears to equalize end thrust. The large gears are carried on solid bearings.

The condensers are located on the ground floor immediately below the turbines. They are of the surface type with two passes, the circulating water entering at the bottom and leaving at the top while the steam enters at the top. In the foreground of Fig. 3, can be seen the circulating discharge pipe going down at an angle, also an angle pattern of atmospheric relief valve with discharge pipe passing through wall into boiler room.

The effective cooling surface, measured on the outside of the condenser tubes is 15,000 sq. ft. there being in each condensor 3,040 tubes of 1 in. outside dia. by No. 20 gauge, active length of tubes being 18 ft. 10 in. Both tubes and tube plates are of muntz metal, the plates having a thickness of 1¼ in.

Condenser capacity is such that 13,800 gals. of water per minute will maintain a vacuum of 28 in. (referred to 30 in. barometer) when handling 143,000 lbs. of condensed steam per hour with injection water at a temperature of 68 deg. F.

Hot Well

Individual hot wells are provided for each condenser, the accessory equipment assembled in each group (see Fig. 5) including air pump, condensate pump, feed water heater and boiler feed pump.

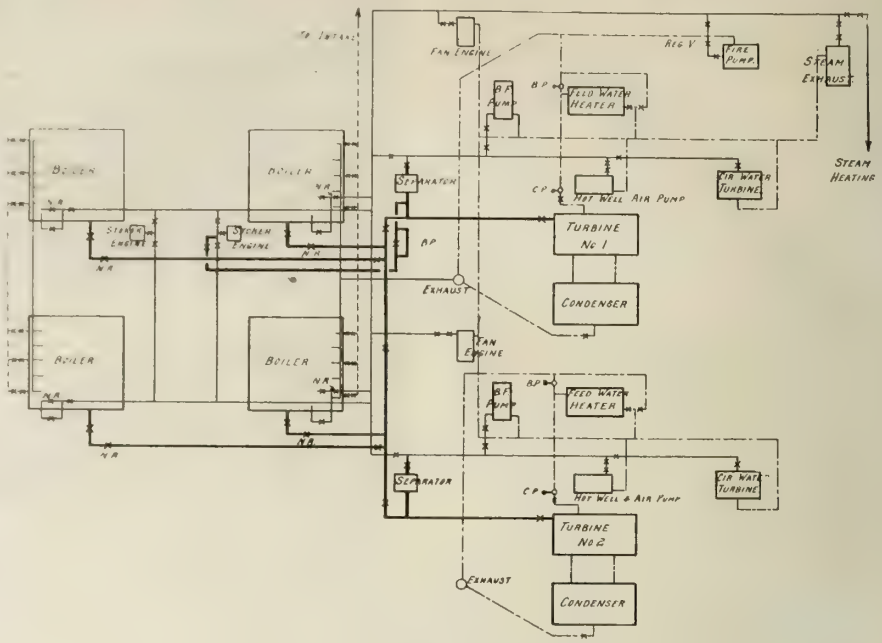

FIG. 6. PLAN LAYOUT OF BOILERS AND AUXILIARY EQUIPMENT.

The air and condensate pumps are mounted on a common shaft and are directly driven by a Westinghouse impulse turbine running at 2,500 revs. per min. The air pump is a Westinghouse-Leblanc rotary with solid bronze runner, and a capacity of 12-2-10 cu. ft. per sec. The condensate pump is centrifugal.

These pumps with the turbine are placed between the Cochrane open type feed water heater and the foundation wall of main turbine, see Fig. 5, the foreground on the illustration being the grating which covers the circulatting pump well. The circulating water pipe from the pump to the condenser can be seen at the left hand bottom corner where it passes through the foundation wall to the condenser.

Behind the feed water heater can be seen the boiler feed pumps and also the fan engine previously referred to.

Boiler Feed Pumps

The boiler feed pumps are of the direct turbine driven centrifugal type. A Westinghouse horizontal impulse turbine running at 2,500 revolutions per minute drives a multistage centrifugal pump of the horizontal volute type with double suction, having 3 stages and a capacity of 525 U. S. gals. per min. The total head operated against, including pipe friction is 520 ft., and water up to 210 deg. F. can be handled. The horse-power of turbine at 200 lbs. per sq. in. is 125.

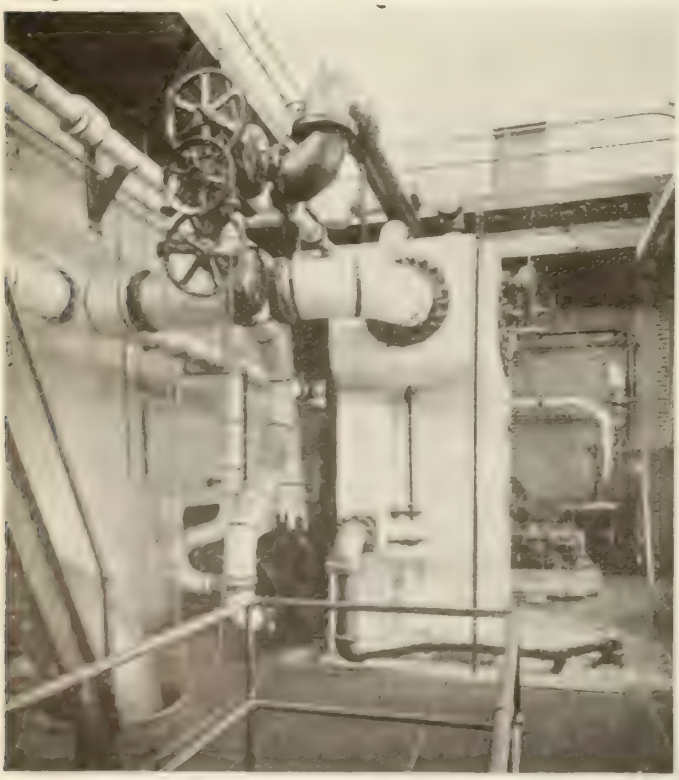

FIG. 5. AUXILIARY EQUIPMENT IN HOT WELL. AIR AND CONDENSATE PUMPS ARE AT LEFT OF FEED WATER HEATER, AND BOILER FEED PUMP BEYOND.

Generator Details

The general appearance of the generators will be gathered from views of main floor Figs. 3 and 4. They are of the revolving field type, with 4 poles, direct connected to the turbine shaft, and having removable end bells to allow access to windings. The field coils are wound with copper strap in slots cut in field core and the insulating material is capable of withstanding a temperature of 150 deg. C. without injury.

The armature core is built of laminated steel in cast iron frame and held firmly in place between two end plates. The armature winding is insulated with material with 90 deg. C. safe limit of temperature rise.

The windings and core are cooled by forced draught generated by two sets of fan blades attached to the rotor shaft which draw air from the air conditioning plant and force it towards the centre from both ends, whence it is expelled outward in a radial direction through air ducts into the passages which give the characteristic external appearance to generators of this type. The warm air is then returned to the conditioning plant where it is cleaned, cooled, and delivered to the intake passages of the generators again.

Air treating plant was installed by the Carrier Air Conditioning Co, and consists of 2 No. 263 F humidifiers with the necessary tanks, sprays, eliminators, pumps, piping and nozzles. Each has a normal capacity of 78,000 cu. ft. per min., with overload of 109,000 cu. ft.

The eliminators consist of vertical galvanized iron plates spaced uniformly in rows, and with parallel surfaces bent to a small angle so that a series of continuous sinuous passages are provided through which the air must pass. The first four corrugations of eliminator plates act as washing surface and are closely spaced so that air passing through is broken up in small thin layers, causing all particles of dust to come in contact with the wet surfaces. The air then enters the spray chamber in which are 560 spray nozzles which maintain a finely atomized spray against the direction of the flow of air. These spray nozzles are placed 3 ft. in front of the final eliminator plates which are provided with an independent set of flooding nozzles which maintain a constant sheet of water flowing down the wet surfaces and allow the spray nozzles to be shut off entirely in very humid weather and the washing procured through flooded eliminators only.

FIG. 7. INTERIOR OF CONTROL GALLERY AND OPERATING ROOM. BEHIND THE INSTRUMENT BOARD AT THE LEFT IS A LARGE BAY WINDOW GIVING UNOBSTRUCTED VIEW OF MAIN FLOOR (SEE FIG. 3.).

The casing for each humidifier which contains the foreging apparatus is 10 ft. long, 13 ft. 8 in. wide, and 13 ft. 1½ in. high. Each unit has a marine light inside, with external switch, and a 15 horse-power motor is provided for operating the centrifugal pump which supplies the water to the nozzles.

Exciters

Westinghouse motor generator exciter set is provided for, each generator being a 75 K.W. 125 volt, shunt interpole generator, driven by a 112 horse-power, 550 volt, 3 phase induction motor. motor.

Power for the exciters is taken from the 6,000 volt station service bus, through a bank of 6600/550 volt step down transformers, each exciter having its individual transformers and switching equipment, with circuit connections as shown in the schematic diagram Fig. 9.

As a precaution to ensure continuity of service, a spare exciter, driven by a steam impulse turbine, is available, which may be quickly connected to any machine in case of necessity. This is effected by tieing in on the 125 volt d.c. field bus, opening the field switch which connects the machine to the exciter and closing the field switch which connects its with the field bus. The two field switches are remote controlled circuit breakers mounted on a panel which also supports the motor operated contactor for inserting or cutting out resistance in the generator field, the rheostat for this purpose being located behind the panel.

The switch for tieing in the spare unit on the field bus is located on a panel in the operating room which panel also carries the switches for the 50 ton capacity service crane in the engine room. The other half of the same panel controls all circuits supplied by the storage battery, including direct current motors, control equipment, auxiliary d.c. lighting circuits, etc., a tie switch enabling the two sections of the panel bus to be tied together as shown in Fig. 9.

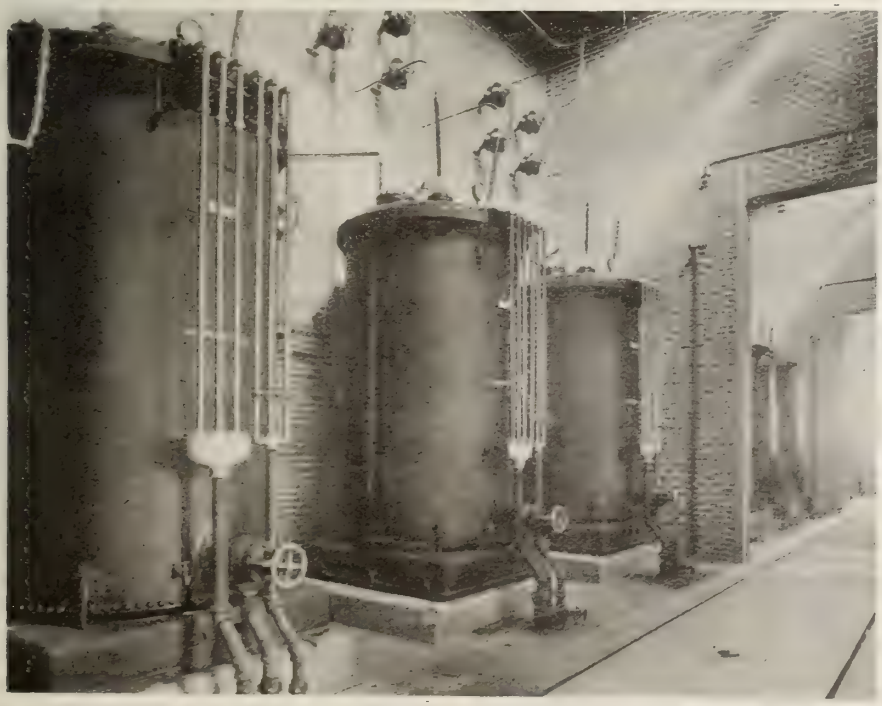

FIG. 8. TRANSFORMER EQUIPMENT. NOTE POCKET ARRANGEMENT OF ROOMS. ALSO WHEEL-MOUNTED BASE PLATES, WHICH FACILITATE REMOVAL OF INDIVIDUAL TRANSFORMERS IN CASE OF MISHAP.

Transformers

Each generator is connected to a bank of three, single phase transformers which step up the voltage from 6600 to 42,000 volts. The machine together with the transformer constitutes a unit and these units are electrically connected only on the 42,000 volt bus, thus introducing two banks of transformers between machines to serve as buffers to the short circuit current, in the event of trouble in one. No special reactance coils are used in the system.

There are at present two banks of step up transformers installed in the power house in a room adjoining the high tension switch room, and separated from it by a brick wall. As shown in Fig. 8, partition walls form pockets to separate each bank of three, single phase, 4,000 k.v.a., 41,000/6,600 volt, oil insulated, water cooled, Westinghouse transformers representing a capacity of 12,500 k.v.a. per bank. They are delta connected on both the high tension and low tension sides.

The conductors from the high tension terminals are of ¾-in. copper tubing and are carried on wall and ceiling insulators through the wall insulator bushings to the 42,000 volt bus bar.

Openings are left in the side walls of the pockets for a passage aisle in front of the row of transformers. A car track runs along this aisle and should it be required to remove a transformer

for inspection or repair all that it is necessary to do is to cut the transformer out of the circuit, disconnect the unions on the oil and water pipes and roll the transformer, whose base is mounted on wheels, on the truck. It may then be removed out under the 10 ton capacity hoist in the inspection room at the end of the row, which is separated from the transformer room by a rolling steel door. The remaining two transformers in the bank would then constitute an open delta connection for carrying the load.

Step Down Feeder Transformers

In addition to its generating capacity, the station is designed to act as a step down transformer station for distributing power to the surriunding manufacturing district. The ultimate capacity of the plant devoted to this service will be, when completed, 25,000 k.v.a., but at the time of writing, equipment for a capacity of 12,500 k.v.a. is installed and one 13,200 volt feeder line leaves the station to supply power to the nearby plant of the National Steel Car Co.

The transformation is effected through a bank of three 42,000 13,200 transformers, identical in design and rating to those in the generator circuits. They occupy the last pocket at the North end of the system and are connected on the high tension side through disconnecting switches and a G. A. type circuit breaker to the 42,000 volt bus. The low tension 13,000 volt bus is at the north end of the 6,600 volt bus structure Fig. 12, as also are the switching apparatus, choke coils, and lightning arresters for the feeders. The feeder lines leave the building at this point through the roof and are carried across the roof to the partment, Fig. 12, and on the floor above are 3 pole, oil circuit breakers shown in Fig .11 for the generators and supply circuits.

The current from the generators is carried to the controlling breakers by 12,500,000 c.m. lead covered cables.

Two station service switches, electrically interlocked, serve to energize the light and power transformers from either side of the system as desired.

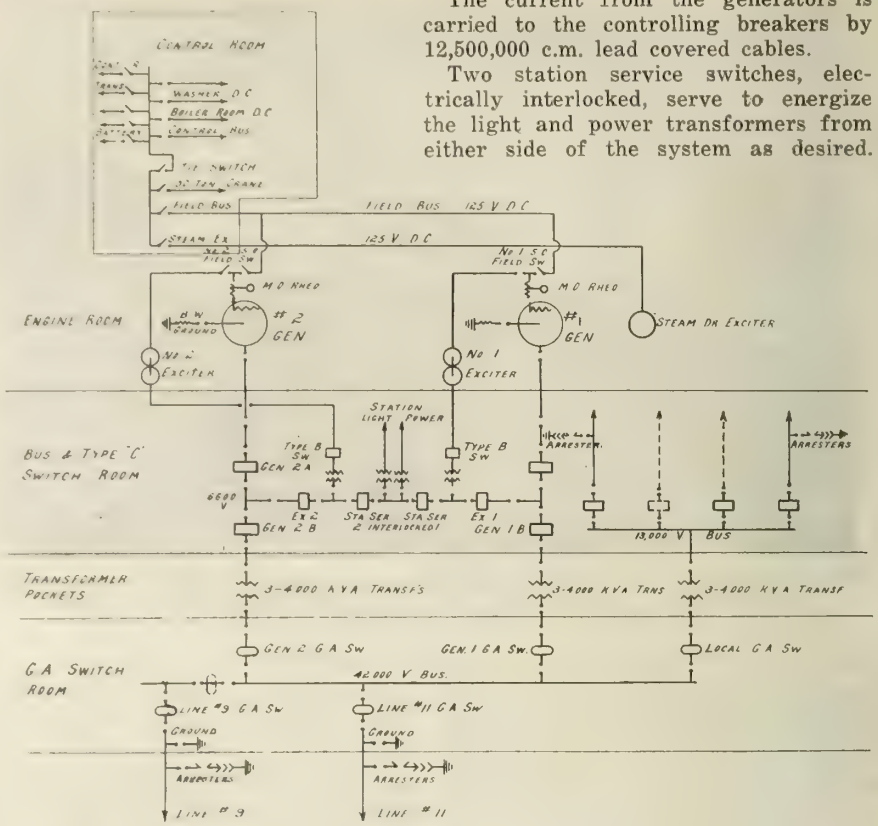

FIG. 9. DIAGRAM OF STATION WIRING SHOWING SWITCHES.

FIG. 10. INTERIOR OF SWITCH ROOM, SHOWING OIL SWITCHES AND BUSES FOR 13,000 VOLT CURRENT.

outgoing pole line. The cells containing the aluminum cell lightning arresters are provided with asbestos doors and the choke coils are helices of aluminum rod.

Low Tension Bus Arrangement

The 6,600 volt bus bar and switching room is divided into upper and lower compartments which contain the necessary switching and auxiliary equipment for supplying alternating current to exciter motors and station light and power service at a lower voltage than 6,600 volts. The low tension distributing, station service, transformers with disconnecting switches, shunt, and current transformers, are installed in a concrete structure in the lower com-

The controller operates the trip coil of one switch and at the same time energizes the closing coil of the other switch but the closing current cannot flow until the first switch is open, thus the closing of the switch does not commence until the other switch is open.

Control

The operating room shown in Fig. 7 is on the second floor, open to unobstructed daylight on the three sides and with a large bay commanding a view of the turbine room from the fourth side. Here the operator electrically controls the 6,600 volt generator circuits, the 42,000 volt oil switches on the transformers and transmission lines and the oil switches on the 13,000 volt feeders from the bench board.

The main switchboard faces the bay window overlooking the turbine room and is of the benchboard type with dummy buses with the indicating instruments mounted on pedestals in front of the benchboard. All oil switches are equipped with a telltale lamp system, indicating the "open" and "closed" position of the switches on the benchboard in the operating room, by small telephone lamps.

Directly behind the operator are mounted the totalizing panels which show by indicating and graphic recording meters, the total amount of power supplied by each unit to the outgoing lines. A feature of these panels is the row of test connections at the

base of the panels which facilitates inserting a test meter in any circuit desired, should the board meter be damaged or as a check on its accuracy.

The proximity of the panel to the stairway which leads to the room, warranted the enclosing of the rear of this panel by a structure, which gives it a more sightly appearance and at the same time allows of easy access for inspection.

The operating room is sufficiently large to accommodate the necessary control apparatus for the completed installation. The entire number of benchboard sections are in place and it only remains to drill and wire the board as further units are added. Another panel, not shown in Fig. 11 contains the tie switches for the direct current auxiliaries previously mentioned and this is mechanically operated.

Safety Measures

Reference to Fig. 9 will afford an idea of the ample safety protective devices employed, both for protecting the apparatus and for ensuring safety for the operating force when engaged in examining or repairing any part of the system. Every piece of apparatus may be segregated by means of disconnecting switches, one on each side of every oil switch, and when these are opened the wiring above and around the oil switch is dead and the oil switch can be inspected, and dismantled without danger. The outgoing lines are protected against lightning and static surges by electrolytic arresters. Another detail involving the safety of the operators and the proper operation of the station is the locking of the 13,000 volt disconnecting switches. Where the ordinary knife switch may open up by reason of the magnetic repulsion when carrying heavy loads, thus often seriously damaging adjacent apparatus by the intense heat of the arc, the lock type switch here employed in the feeder lines ensures a positive connection under heavy currents.

Auxiliary Equipment

In a separate room on the ground floor is located the storage battery reserve for supplying direct current to the control, crane service, and other circuits in case of an interruption of the main circuit. This battery consists of 66 cells, has a normal voltage of 125 volts, and a normal discharge rate of 200 amp for one hour.

The 50 ton power house crane is manufactured by Cleveland Crane and Engineering Co. and is the cage operated type. It is provided with mechanical brakes of the double friction, band type, self lubricating and running in oil. A solenoid operated electric brake is also connected to the armature shaft of the hoist motor and connected so as to apply itself in failure of current. It is equally effective in stopping motor in hoisting or lowering and is capable of sustaining the full load of the hoist. Each hoist is provided with Auto circuit breakers, which break the circuit when the hook is raised above or descends below a predetermined point.

FIG. 11. VIEW IN 6.600-VOLT SWITCH ROOM. SHOWING RANGE OF ENCLOSED SWITCHES.

A 10 ton capacity, hand operated hoist is provided in the inspection room on the transformer floor. In this room are also the oil tanks for the transformer oil, consisting of two tanks, one for clean, and one for dirty oil. Two small oil tanks for the oil switches and lightning arresters are mounted above the transformer oil tanks. Electro-Seal insulating oil is used.

The transformers and high tension oil switches are provided with sewer connections and provision is made so that in case of an explosion in the tank or a fire, the oil can escape to the sewers.

Two pumps form part of the equipment for handling the oil. One delivers oil from the tanks, up to the transformers and a centrifugal pump operates the small filter press output for filtering and drying the oil.

Transmission Lines

The two 42,000 volt transmission lines leaving the station are carried on one set of steel towers and deliver their output to the high tension out-door switching station at Bartonville, there to be linked in parallel with the long distance transmission lines from the hydraulic station at DeCew Falls.

In order to join the two stations together it is necessary to synchronize the two and therefore synchronizing equipment is provided in the control room. The signalling devices are an aid to the operator when bringing an incoming machine up to synchronism, as by means of it he may inform the turbine attendants, on the floor below, what is desired of them. The various

FIG. 12. ONE SIDE OF THE 6.600-VOLT BUS STRUCTURE LOCATED DIRECTLY BELOW SWITCH ROOM SHOWN IN FIG. 11.

orders are illuminated on the signal board, provided for each machine, by pressing an electric button. The attendant then executes the order and presses the corresponding button on his board, signifying to the operator that the order is carried out. When it is desired to call the attention of an attendant to any particular machine, a Klaxon horn is sounded and a lamp lights up over the machine intended.

It is quite interesting to note that the power station at DeCew Falls can feed back on the 42,000 volt bus in the steam station and cause the generators to operate as synchronous motors, when the turbines are throttled and just sufficient steam admitted to circulate through the turbine blades and keep them from becoming excessively hot through friction effect. This is a particularly valuable feature in this case, for until demand on the station necessitates every unit carrying a power load, those machines not generating may be put to economic use as synchronous condensers for regulating the power factor of the load, thus maintaining the required voltage at the receiving end of the hydraulic line from DeCew Falls under a wide range of load.

From the operating standpoint, this system is very advantageous, as it admits of regulation at the Hamilton end of the line, the generator field being overexcited to increase the power factor and decrease the voltage drop in the lines on heavy loads and underexcited to decrease the power factor and increase the voltage drop on light loads. The improvemnt in regulation thus effected will enable the lines from DeCew Falls to carry more power than before and incidentally show an immediate profitable return on the capital which has been expended, to provide for future power demands.

The power house is built entirely of brick and steel with reinforced concrete floors and is as fireproof as far as any station can be. The inside walls of the engine room are faced with white enamel brick up to the crane level, above which, the walls are satin brick and the ceiling a buff gypsum. The floor is laid with English red quarry tiles and conforms with the general interior finish of the power house to give it a neat and bright appearance. The steel throughout, and most of the cement floor surface, is painted gray.

Every convenience is provided for the operating staff, the equipment including adequate office accommodation for the superintendent, locker room and wash room for the employes, well equipped repair shop and intercommunicating and local telephone system. Excellent lighting is provided throughout, all the larger rooms being very effectively illuminated by properly contained nitrogen lamps suspended from the roof trusses. The plant has been in operation since June 1917, and was designed and built by the following members of the Co.'s organization: W. C. Hawkins, chief engineer and managing director: Geo. Service, mechanical engineer; Chas. H. Hutton, electrical engineer, to whom we are indebted for the illustrations and data accompanying the article.

SOUTHERN CANADA POWER CO. DEVELOPMENTS

THE map accompanying the annual report of Southern Canada Power Co. recently issued shows that the company's operations cover an exceptionally wide range of territory, doubtless the largest east of the Niagara power zone. On the south power is carried across the international boundary into Derby, Vermont. On the west the transmission lines approach as near to Montreal as St. Johns, Iberville, St. Hilaire and Beloeil. On the north Drummondville and adjacent municipalities are tapped, while on the east the principal points of consumption are Sherbrooke, Lennoxville, Richmond and Compton. These distances are approximately 70 to 75 miles east and west, north and south.

It is quietly but gradually developing into an important development, and is extending a network of power wires throughout the south-eastern section of the Province of Quebec, and working up the available hydro-electric propositions in that area.

The report states:

"Considerable progress has been made during the year in the consolidation of the subsidiaries acquired, as referred to in the last report. Since then the company has purchased the municipal plants of the City of Granby and the Town of Bromptonville, and is now engaged in the joining up of its various isolated properties.

"The company at present has under construction about eight-five miles of transmission lines from Sherbrooke to Granby and Cowansville, from Sherbrooke to Bromptonville, and from St. Cyrille to St. Germain through Drummondville, with the necessary sub-stations and distribution systems.

"The power development at Richmond, Drummondville, Foster and Granby are being considerably improved and enlarged and put into shape for the most economical operation, through the transmission lines, with the other plants of the company.

in connection with the engineering investigation of the company's water powers, and additional riparian and other rights have been acquired, so that practically all such work usually preliminary to such developments is now completed."

CANADA'S COAL PROBLEM

The "Monetary Times" recently published a four-page article by Arthur V. White on "Canada's Coal Problem." Mr. White is consulting engineer to the Conservation Commission, and has filled many important engineering appointments in Europe and America.

Canada at present imports annually from the United States 4,500,000 tons of anthracite and from ten to fourteen million tons of bituminous coal, the latter largely for power purposes. It is believed that the American anthracite fields—even at the pre-war rate of production—will be exhausted in a hundred years. The friendliness of the United States towards this country has recently been emphasized in this very question of the coal supply, but circumstances are conceivable in which our neighbor to the south might feel compelled, in the interests of her own population, to completely shut off the export of anthracite, and to barter her bituminous output for particularly necessary Canadian products, such as electrical power.

Canada now exports to the United States about 275,000 horse-power of electrical energy, which Mr. White calculates as equal to three million tons of coal, and goes on to estimate the developed electrical horse-power of Canada at 1,813,200, and the possible horse-power at 18,800,000. But by no means all of our water powers, he says, may be economically developed. He calls attention to the importance of conserving all of this horse-power and turning it to public uses.

MAILS BY AIR AROUND WORLD

ADDRESSING a large asembly of members of the Canadian Club at luncheon recently in Toronto, Lord Montague impressed upon his hearers the present and future importance of aviation. In the early days of the war many people had undertestimated the value of aircraft—the airplane and seaplane—in modern warfare. There was no doubt any longer as to the possibilities of the aircraft.

Lord Montagu predicted that the time was not far distant when airplanes would be used to carry the mails around the world. Lord Montague stated that he was a member of a committee in London which has under consideration a scheme for the establishment of an Imperial aircraft service when the roar of guns in the war zone ceases. He believes that all the colonies of the British Empire should be linked up in the scheme.

"Commercially the airplane will play a wonderful part in the developmen of business life of Canada after the war," said Lord Montagu. "Toronto has now become the aviation centre of the North American continent, and after the war the aviation factories and schools of instruction should be continued. They will be necessary. The Germans may be our superior in some respects in the matter of building machines, but they cannot beat us in the quality of the men. Canadian aviators have demonstrated to the Germans that they are constituted in make-up and fighting qualities of the right kind of stuff. Generals who watched them have told me that as fighters at a high altitude they are remarkable for courage, ingenuity and skill."

Eyes of the Army

Referring to the invaluable service rendered by the airplane and seaplane in the present struggle in Europe, Lord Mon-

tagu declared that the Generals are kept in close touch with what is going on behind the lines of the enemy. The Allied aviators had demonstrated their superiority over the Germans in this respect and could rightfully lay claim to the title, "Masters of the air." What the Allied armies lacked in man-power was more than made up in the invaluable branch of the army. Lord Montagu impressed upon upon his hearers the fact that with the exception of the United States there was a lack of man-power in the army of every Allied power fighting in Flanders. Consequently every month as the war goes on brings more vididly to the minds of the people the relative importance of the airplane and seaplane.

An Army of Pilots

In conclusion Lord Montagu made a special plea for co-operation in the matter of striving to keep the aviation service and schools of instruction in Toronto and elsewhere at a very high standard of efficiency. He said there were between 1,500 and 2,000 Canadian pilots at the front, while an additional 500 were in Toronto preparing to go to the front.

INDUSTRIAL ALCOHOL

THE problem of a future supply of gasoline is yearly becoming more acute, in fact the question of finding a substitute for petroleum itself is recognized as being a matter of a few years only. Just when circumstances will justify efforts to establish an alcohol industry cannot be very well decided till the influence of war conditions has been removed. Discussing the prospects of producing industrial alcohol in this country, W. J. Dick, writing in the Canadian Mining Institute Bulletin, states that imports of petroleum and petroleum products into Canada have been rapidly increasing, while the domestic production has been decreasing. The imports of petroleum, crude and refined, during the calendar year 1914 totalled nearly 244½ million gallons valued at over $11,000,000. As our crude petroleum production in 1914 amounted to about 7½ million gallons, valued at about $344,000, it can be seen that Canada is dependent upon foreign sources for her supplies of petroleum and petroleum products. The production of crude petroleum has come almost solely from Ontario and is steadily but surely declining in spite of attempt being made by drilling to enlarge the areas of producing fields, or to find new ones.

In considering the development of a substitute for petroleum for certain purposes such as illumination, cooking and for use in internal combustion engines, industrial alcohol, which is used to a considerable extent in Germany and Great Britain, is suggested.

In 1914, the imports of refined and illuminating oils amounted to over 12,800,000 gallons, valued at $970.000; during the same year 24,400,000 gallons of gasoline, valued at $2,747,000 were imported. If industrial alcohol could be produced economically in Canada so as to replace these products there would be a saving of over 3½ million dollars worth of imports. On account of the rising price of gasoline it has been reported that many tractors have been rendered idle in the Prairie Provinces, thus reducing the acreage to be sown. Some people are of the opinion that the high cost of gasoline is occasioned by the present war, but the Director of the United States Bureau of Mines declares that the prevailing prices may not only continue for some time, but will undoubtedly reach higher levels before there is any permanent relief. He states that the United States Government will, during the next fiscal year, pay 31½ cents for its gasoline. He, therefore, concludes that, if the United States, using such vast quantities, is compelled to pay this high price, the private consumer will have to pay much more. Furthermore, at the present rate of production, the known supply of crude oil in the United States, from which we are getting our present supply of gasoline, will be exhausted in 27 years.

In considering the establishment of an alcohol industry in Canada, it is necessary to distinguish war conditions from those obtaining in normal times. As alcohol is essential in the manufacture of smokeless powder, present prices are abnormally high; whereas, under normal conditions, there is not the great demand for alcohol for this special purpose and it would then have to compete with kerosene and similar products.

The raw materials used elsewhere than in Canada for the manufacture of industrial alcohol are potatoes, sugar beets, molasses, and sawdust.

The present price and yield of potatoes in Canada are not such as would warrant the founding of a potato alcohol industry in Canada. The British Committee on Industrial Alcohol reported that it would not be possible to establish potato-alcohol industry in Great Britain unless potatoes were less than 29 cents per bushel. W. T. Macoun, Dominion Horticulturist, states that, if best methods are followed, 300 bushels of potatoes per acre can be produced. He estimates the cost of production and marketing such a crop of 20½ cents per bushel but says that this will be reduced on large areas where the most modern machinery is used. *The Census and Statistics Monthly* states that the profit per acre, in 1913, for spring wheat grown in Manitoba, Saskatchewan and Alberta was $2.65, $1.72 and $2.09 respectively, so that it is evident that if potatoes were sold at 21½ cents per bushel there would be a greater profit to the farmer than growing wheat in these provinces.

Potatoes used in the manufacture of alcohol need not be sacked and may be shipped frozen with but a trifling loss.

The establishment of an alcohol industry on a suitable scale would be, as outlined previously, a means of carrying on profitable agriculture in areas otherwise unsuited to crop growing; the feeding of the spent mash to cattle would encourage live stock growing and the alcohol produced could be consumed by the farmers as illuminant, for cooking and heating purposes, and as a source of motor fuel.

THIRD LARGEST DAM IN WORLD IN QUEBEC

THE most important water conservation work thus far undertaken in Canada is that undertaken by the Quebec Government and now nearing completion at La Loutre, on the St. Maurice River. It will store up the waters of the St. Maurice for the benefit of its many water powers and will double the low-water flow.

This work had been projected for many years, as the regulation of the river is of the greatest value to the important developed water powers at La Tuque, Grand'mére and Shawinigan Falls, but no construction work was undertaken. After full investigation of the project, both from the engineering and financial viewpoint, the Quebec Streams Commission let the contract for construction in the summer of 1915.

The work has progressed steadily since in spite of the great difficulties in transportation. It is now 80 per cent. completed, and will cost about $1,500,000. When finished, it will create a reservoir of 160,000 million cu. ft., forming the third largest artificial reservoir in the world, being exceeded only by the Assuan reservoir on the Nile and the Gatun lake on the Panama Canal. From the owners of the power sites already developed, the Commission will receive a revenue of upwards of $130,000.

Between the reservoir and the mouth of the St. Maurice there are 17 power sites with heads of from 10 feet to 150 feet. The aggregate descent at these sites totals 800 feet, but the dams erected in developing the various sites will increase this total head to 900 feet. Under present conditions, these sites have a total capacity of approximately 350,000 theoretical h.p., but it is estimated that some 900,000 h.p. will be available when the flow is regulated from the reservoir. At Shawinigan, Grand'mére and La Tuque alone, the three sites at present utilized on the St. Maurice, the potentiality will be raised from an aggregate of some 190,000 theoretical h.p. to over 400,000 h.p.

Will Expedite Coal Shipments to Canada.—C. A. Magrath, Dominion Fuel Controller, who has been in Washington and New York for some days in connection with the fuel situation, has succeeded in arranging for a number of emergency shipments of coal to Canada. This has been done despite the pressure coming from the consumers in the United States to limit the exportation from the country in order to relieve the acute situation across the border. While there is a shortage of coal in some districts, there must be a large supply in the country and the problem is largely one of transportation and distribution. This is accentuated both in connection with distribution in Canada and additional shipments from across the line, by war conditions.

Modern Steam Power Plant and Its Appliances-III

By John H. Hale*

Despite the wonderful developments of hydro-electric power generation, the modern steam power plant occupies a firmly established position in engineering effort from which its removal, if it take place at all, will never be more than temporary. The economies possible in large plants and the duty of all engineers to adapt such methods to their small individual plants wherever possible is emphasized by the writer.

THE efficiency of the steam engine is often based on the amount of fuel burned per indicated horse-power per hour, but is more properly based on steam consumption. The highest class of steam engine, running condensing, will use under test conditions, from twelve to twelve and one half pounds of water, in the form of steam per indicated horse-power per hour, while the ordinary automatic cut-off engine, with single expansion, noncondensing, uses from twenty-eight to thirty-five pounds. The fuel used per horse-power per hour, therefore, depends on the quality of coal, and the efficiency of the boiler and furnace, as well as upon the efficiency of the engines.

A good boiler, properly set and fired, will show a much higher efficiency in per cent. than the engine. When operated with high-grade coal, and under the best of conditions, a boiler may deliver to the engine as much as 75 per cent. of the theoretical heat of the coal, and if the coal contains 14,500 B.T.U. per pound, this is equivalent to 9.78 lbs. of water evaporated from a feed water temperature of 120 deg. to steam at 200 pounds pressure (gauge). If the engine uses 12 pounds of steam per horse-power, this means a coal consumption of 1.23 pounds per indicated horse-power per hour, or if the engine uses 30 pounds of steam a coal consumption of 3.07 pounds. These figures if transposed for efficiency would be as follows: one pound of coal having 14,500 B.T.U. is equivalent to 11,281,000, foot pounds, which on a supposition of 75 per cent. efficiency in the boiler, is equal to 8,460,750 foot pounds, which if all utilized by the engine would produce 429 H.P. per hour, instead of the amounts above stated.

On this basis the higest class engine has an efficiency of scarcely 19 per cent. and the other of a little more than 7½ per cent. and the efficiency and boiler combined is but 14¼ per cent. and 5.7 per cent. respectively.

It is economy, therefore, in most cases to use a high class engine. There are instances, however, where the engine is used for so short a time in each year, that the saving may not be sufficient to pay the interest on the additional cost, and a cheaper engine, even if comparatively wasteful, may be better economy.

Compound Engines

Compound engines, when high pressure can be obtained, have an advantage in economy over single cylinders, and triple and quadruple expansion engines, under some conditions, show a saving over simple compound, but they require a pressure of 150 to 200 pounds, and a comparatively steady load to develop their advantage to a great degree.

A large boiler is generally an advantage, but it is not economy to use a large engine to develop small power. Sufficient steam to fill the cylinder at the terminal pressure of each stroke has to be furnished, whether the engine is doing more or less work, and this frequently amounts to far more than the steam used to do the work.

Thus a 24-in. by 48-in. engine, making 60 revs. per min. with cut-off, uses 30 h.p. of steam in displacing the atmosphere without exerting any available power. For the same reason back pressure greatly increases the cost of power.

When selecting an engine for any particular power-plant, the first thing to decide is the amount of power required. If an engine is already installed, and the new engine is only a replacement, this is an easy matter, as indicator cards may be taken from the engine which is to be replaced. If the power house is an entirely new one, then a list of the machinery to be driven will have to be made out, and the total power determined from the amount taken to drive each one individually.

Great care should be taken when figuring out the power to take into account the length of time, and also the particular time of day during which each machine will run, as this has a great bearing on the determination of the proper size of the engine. When the list of powers and time of running of each machine is fixed, a power curve should be laid out, showing the variation in load on power house during the twenty-four hours, or portion of it which constitutes the daily run.

The power curve will give the minimum average and maximum, or peak loads, and an examination will tell whether it is best to develop the power with one unit, or divide it between two or more units.

Running Conditions

When power to be developed has been decided, it is then necessary to examine the running conditions of the plant. The first thing to find out is the steam pressure available; whether the steam is superheated and if so, the degree of superheat; also whether the engine is to run condensing or non-condensing, and if the latter, the amount of back pressure. If there is an exhaust steam heating system in connection with the plant, the amount of exhaust steam needed, and the number of months in the year it is in operation, will have to be determined. When this information has been collected, it will be seen how much steam economy will affect the selection, for, if the heating system takes as much or more steam than the engine does to develop the power required, the steam economy is not of such importance as it otherwise might be, but in the majority of plants in this country of any size, the elements of steam economy enter largely into the problem by reason of the fact that the steam required for power is largely in excess of that required for heating, and that the heating plant is shut down for about half the year.

This being the case, it is necessary for the engineer to determine the most economical engine for his purpose. His choice will be somewhat influenced by price, but in the long run it pays best to buy a well made engine, built by a reputable firm, and one that is economical in the use of steam.

Any good firm of engine builders will give a guaranteed steam preformance of their engine, but this guarantee should be carefully examined to see that the guarantee performance is under the same conditions, and that the engine is run on saturated steam, as many engines which are built especially to run with superheated steam, and give good results under these conditions, fall down badly when running on ordinary saturated steam, and it is the builders of these engines that are apt to give their guaranteed performance with superheated steam, resulting in disappointed customers who have overlooked the difference in conditions.

Best is Cheapest

For all round economy and reliability the four valve or Corliss type, as now built by the best makers, will always hold first place. The purchase of a cheap machine should be avoided as it is only by careful work in connection with the wearing parts, and such machine work as will ensure tight pistons and valves, that the low steam consumption guaranteed by the best makers is obtained.

The cost of keeping up repairs on this type of engine has often been used as an argument against it, but an examination of the records of the best builders will show an astounding number of engines that have been running for years without a cent's worth of repairs. In citing one particular plant, there are two Goldie & McCulloch Corliss cross compound noncondensing engines, running under 150 lbs. steam pressure, and 150 rev. per min. These engines have been in oper-

*Secretary Canadian Association of Stationary Engineers.

ation for three years, running on an average eighteen hours per day, and I personally consider them as good today as when we received them, and up to this date there has not been a single cent expended on them for repairs.

Turbine Features

The problem of increasing the capacity of an existing power house, which is already crowded for room, has been successfully solved by the advent of the exhaust-steam or low-pressure turbine. The chief reason for the rapid growth in favor of the low-pressure turbine is the fact that the steam turbine is much more economical in the low pressure stages than a reciprocating engine, being capable of producing a horse-power on or about 30 pounds of steam at atmosphere pressure and twenty-eight inches of vacuum.

It will thus be seen that if we have an engine that develops a horse-power on 15 pounds of steam when running condensing, and 20 lbs. when running non-condensing, and put the steam into a low pressure turbine, we would have (allowing 5 pounds per horse-power for condensation in the cylinders) 15 pounds left to put into the turbine, and there develop ½ horse-power, or altogether 1½ horse-power, with our original 20 pounds of steam, or at the rate of 20 ÷ 1.5 =12.5 pounds per horse-power for the combined engine and turbine.

This will give a rough idea of the gain in using an exhaust steam turbine, which not only increases the capacity of the plant 50 per cent. but decreases the steam consumption per horse-power 16¼ per cent. The low pressure turbine, with its condenser and other auxiliaries, would not take up more than about one half the floor space of the original unit.

To every engineer who is operating a steam plant, I would like to say give your engine and boiler room your best and most careful attention, and show administrative ability, and then you will get the best efficiency that may be got out of a steam plant such as yours may be.

CANADA'S TRADE POSITION

COMMENTING on the thrift of Canadians the "Wall Street Journal" says:

Canadian foreign trade for ten months of 1917 approaches $2,000,000,000 — a per capita of $2,500. Of but recent development, the volume of commerce for the whole year will doubtless nearly equal in dollar value our own foreign trade for 1900, when we had 97,000,000 people. With but one-thirteenth our man-power, Canadian exports and imports will exceed one-fifth of our own.

It may be said low cost production and high prices of farm exports and manufactured food and shipments of military supplies have made this possible. But in reckoning these factors the adverse circumstances in which Canada had the opportunity to lay the foundation for future international trade must be given due consideration.

Position in 1914

In the summer of 1914 Canada was tentatively surveying the means of recovery from continent-wide liquidation. In the west and also in the east a prolonged real estate boom had collapsed, coincident and correlative with a severe contraction of commercial credit and radical readjustment of domestic trade in volume and method. It was a moot question whether real business revival would manifest itself in the autumn of 1914 or the following spring.

Credit was in its most sensitive stage of convalescence, when the declaration of war came as a clap of thunder from a cloudless sky, and 100,000 industrial effectives went voluntarily to the colors. The supply of labor was never adequate to pioneer construction; nevertheless, over 400,000 men went into service voluntarily from all classes and from the most productive occupations.

War Bonds

At least $500,000,000 of war bonds have been purchased by the Canadians. The Ministers of the Crown were justified in the implicit confidence which they placed in the Canadian instinct of thrift. There are racial and political differences in Canada, but thrift in common, homely household terms, is a Dominion-wide virtue, characteristic of the passive and the unaggressive, as well as of the industrious and ambitious.

INDUSTRIAL DEVELOPMENT IN JAPAN

THE following observations regarding the formation of industrial companies in Japan since the outbreak of the war have been furnished by E. F. Crowe, Acting Canadian Trade Commissioner, Yokohama:

Metals

Although the iron industry of Japan is still in its infancy, it gives promise of assuming considerable importance in the future. Before the war the annual production of Japan was about 260,000 tons of iron, this being around one-half of its consumption. Since the war several new companies have been formed for the production of iron. Six companies with a combined capital of 40,000,000 yen have established new works.

With regard to steel, three new companies have commenced operations and four new works have been established. Their total combined capital is estimated at 5,000,000 yen. One company is producing steamer shafts, railway wheels, and tires as well as supplying the home trade. They have received orders from China and India. It is stated that the intention of this company is to devote all its energy to the export trade rather than to the domestic field.

It is generally conceded that the future of the zinc industry of Japan is good and that a large export trade is to be expected after the war. One company is already manufacturing zinc for exportation. Japanese zinc ore contains many other metals. such as gold, silver, and copper and the refining of these metals is carried on along with the treatment of the ore. Five new zinc companies are operating six works for the treatment of Japanese zinc ore and have a total combined capital of 7,600,000 yen.

In March, 1916, a company was formed with a capital of 1,000,000 yen for the manufacture of aluminum. It is stated that the process to be used is different from that in vogue in Europe and the United States. The alumina is obtained from a clay which is a product especially of Japan and is treated by an electrolytic process.

A company was formed in January, 1917, with a capital of 100,000 yen for the purpose of producing sheet lead for the use of chemical industries. Sheets are being turned out measuring ten feet by four feet and it is claimed that they are superior to any which have hitherto been manufactured in Japan.

Metal Goods

A company which was first established in 1913 for the manufacture of galvanized iron sheets and galvanized iron wire has increased its capital from 300,000 yen to 700,000 yen. Up to the present its output has been confined to the home market but it intends to export its products later.

Two companies with a combined capital of 1,500,000 yen have been formed for the purpose of manufacturing wire netting.

Machinery

For the manufacture of machinery, three new companies with a combined capital of 2,300,000 yen have been established. In addition to the manufacture of munitions, rotary printing machines, etc., and gun metal are also being manufactured.

Electrical Supplies and Accessories

There have been formed during the period under review six companies for the manufacture of electrical supplies and accessories, such as electric motors, dynamos, switches, lamp bulbs, carbon electrodes, carbon brushes, etc. Their total combined capital is 4,530,000 yen and they operate eleven factories. An improved process for the manufacture of micanite has enabled a Japanese com-

Mining

There have been organized three coal mining companies with a combined capital of 1,550,000 yen. One company is also producing coke in large quantities. In December, 1916, a company was formed with a capital of 120,000 yen to exploit a sulphur mine. A special process is used in refining the raw material.

Note.—A yen equals approximately 50 cents at the normal rate of exchange.

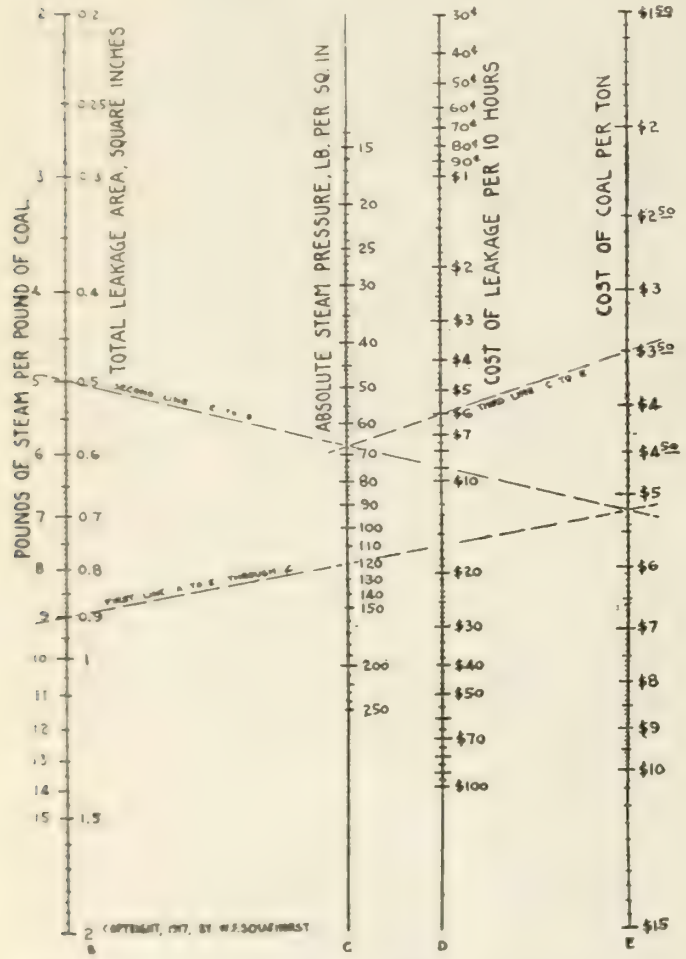
EACH MAN TO HIS MATERIAL

By D. A. Hampson

THE most famous saying of the late Bob Fitzsimmons was to "strike from where your hand is." The machinist doing work around in various factories cannot help notice that the employees of the various places follow this advice unknowingly. For instance in a large creamery, the writer saw the engineer cutting

threads on some pipe and for a lubricant he had a squirt can filled with butter: he was cutting nice threads too—his pipe vise was near the engine and he kept the can resting on the cylinder head where the butter was heated to a liquid.

In a leather tanning plant, they burned leather scraps under a 40 h.p. boiler and while it wasn't coal by any means, it did very well with the aid of a blower. Elsewhere in the plant leather scrap was used—in babbitting, a piece of leather took the place of putty, ends of leather were slitted up into belt laces, etc. Down at the paper mill they worked over vast quantities of old rope into pulp but it was only natural that for repairs and in an emergency rope was used for supports and slings and ties where an outsider would have insisted that iron rods and wood blocks were the only materials that would fill the bill.



THE COST OF LEAKING STEAM

By N. G. Near.

TO determine the cost of leaking steam with any degree of accuracy we must know at least four factors: (1) The number of pounds of steam evaporated by 1 lb. of coal; the greater this is the less is the cost of leaky pipes, other conditions being the same; (2) the total area of leakage; (3) the absolute steam pressure, which is equal to the gauge pressure, plus the atmospheric pressure; at sea level this is usually reckoned as gauge pressure, in pounds per square inch, plus 14.7; and (4) the cost of coal per ton of 2,000 lbs.

For example, how much money is lost every 10 hours under the following conditions: Nine lbs. of steam are generated by each pound of coal. The total area of leakage is ¼ sq. in. The gauge pressure is 105 lbs. per square inch (making the absolute pressure very close to 105 + 14.7 = 120 lbs. per square inch). The cost of coal is $3.50 per ton.

Referring now to the chart, lay a straightedge across the chart three times as indicated by the dotted lines and the problem is solved. Run the first line from the 9 (column A) through the 120 (column C) and locate the intersection in column E. Run the second line from that point of intersection to the 0.5 (column B) and locate the intersection in column C. From that point of intersection run the third line to the $3.50 (column E) and the answer is found at the intersection with column D. The answer is $6 loss per 10 hours.

In case it is found that the total leakage area is less than shown in column B, the chart may be used by shifting decimal points. For example, if, in the above problem, the leakage area had been 0.05 instead of 0.5 sq. in. the answer would be 60 cents instead of $6 per 10-hour day.

When using the chart, the steps must follow in the order shown and above described. First line, A to E through C. Second line, E to B. Third line, C to E.

The range of the chart is great enough to easily handle any ordinary problem.

The United States super - dreadnought Tennessee will be driven by four alternating-current motors, one to each propeller shaft, supplied by current at 3,400 volts from two 13,500 horse-power turbo-generators. The motors will be wound for both 36 poles and 24 poles, operating on the former as squirrel-cage machines and on the latter as wound rotor machines.

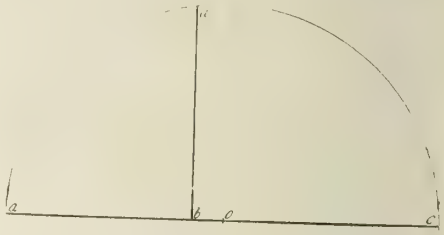
STORING COAL IN BULK

WHEN coal is stored in bulk the piles should not be higher than 10 ft. according to the British Fire Prevention Committee. Iron pipes 3-in. or 4-in. in diameter, or, failing these, eathenware pipes or ducts formed of incombustible material, should be inserted vertically in the piles as they are built up, their lower ends being at different heights above the ground throughout the piles, with about one pipe or duct to every 300 sq. ft. of surface; a thermometer should be occasionally lowered down these pipes or ducts to ascertain the temperature from the centre of the pile; and if wet, very small, soft, or impure coal is received it should be dumped round the edges of the pile, or in some position where the air can get to it freely and where other coal will not be packed on top of it.

MEAN PROPORTION

By J. H. R.

IT is sometimes required to find the mean proportion between the lengths of two lines. This can be done either by calculation or by the graphic method. Taking X as the mean dimension between A and B, the proportion would be A : X : : X : B, or $X^2 = A\ B$. Suppose it is desired to find the mean proportion between two lines 3 and 4 inches long. Using the above proportion we have 3 : X : : X : 4, or $X^2 = 4 = 12$. Hence, $X = \sqrt{12} = 3.464$ inches. Proof:—the product of the two extremes of any direct proportion must equal the product of the two means; thus, 3 : 3.464 : : 3.464 : 4, and $3 \times 4 = 1^2$, while $3.464 \times 3.464 = 11.9993$. The slight difference in the two values is due to the number of decimal places.



MEAN PROPORTION DIAGRAM.

To find the mean proportion by the graphical method, proceed as follows: On a straight horizontal line lay off the lengths of the two known lines A-B and B-C. Bisect the total length A-C at the point O; from this point, with a radius O-A or O-C, describe the semi-circle shown. The perpendicular line B-D drawn from the juncture of the other two lines will be the mean proportional length.

Canada Gets Largest Increase in U. S. Coal.—Steady increase in coal exports from the United States during the last two years, despite an equally steady curtailment in fuel supplies to South American countries in an effort to handicap Germany's trade carried by neutral steamers, is shown in figures issued by the Bureau of Foreign and Domestic Commerce, Washington. Canada now is receiving the largest increase in fuel supplies, with smaller increases going to Panama and Cuba. Italy has received only 500,000 tons in ten months this year, compared with 1,665,000 last year.

NEW PROJECT FOR ABSTRACTING NITROGEN FROM AIR

IT is interesting to note that the fixation of atmospheric nitrogen is being undertaken on a commercial scale in England. The process to be employed bears the name of a well known inventor, Mr. Kilburn Scott, and depends on the action of intense electric arcs to liberate the nitrogen from the air and accomplish its fixation for commercial purposes in the form of nitric acid gas.

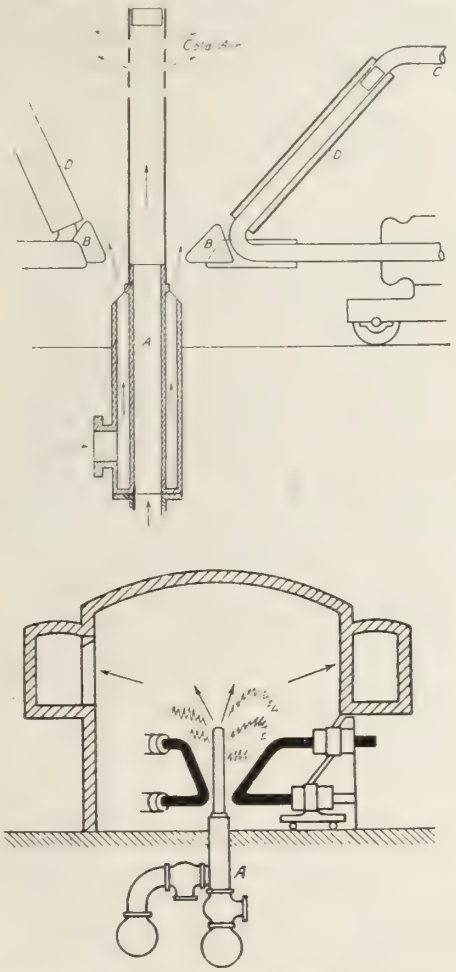
The operation is carried on in a special fire brick lined furnace in which are mounted the three horn-shaped electrodes spaced at 120 degrees to one another and surrounding a central air supply pipe. Each horn electrode approaches close to, but does not touch, the central pipe at its lowest tip and diverges sharply upwards. The general arrangement is shown in the accompanying illustration reproduced from the patent specification.

An alternating 3-phase current is utilized, each electrode being connected with one of the supply wires. The air pipe A is grounded and forms the neutral point of a star-connected 3-phase system of which the three alternating but practically continuous arc flames represent the load on the system. The arcs are driven upwards by three blasts of air which issue from the outer tube of the central pipe. The inner tube projects upwards to a point about level with the top of the electrodes and at this point there are three more nozzles supplying air under pressure. These blasts provide the cold zone which is necessary for the fixation of nitric acid gas. The air which drives the arcs upwards is preferably at a high temperature, but the air which emerges from the top of the pipe must be as cool as possible.

Due to the intense heat to which the pipe and electrode parts are subjected, provision is made for renewing parts that are liable to be burned away. The cold air pipe is surrounded by a tube which is easily renewable, and the electrodes C which are made of steel tubing through which cooling water is circulated, have renewable clips D to protect them.

The mixture of nitric acid gas and cool air is drawn off through large sized openings and passes to flues which connect with the various furnaces.

The initial installation is of 1.000 electrical horsepower capacity which will be increased if the results come up to anticipation. It is claimed on behalf of the process, that it enables nitric acid to be produced with considerable profit, the output per kilowatt



ARRANGEMENT OF ELECTRODES IN APPARATUS FOR FIXATION OF NITROGEN FROM THE ATMOSPHERE.

year being 1½ tons, which at the prevailing prices for electric power and manufactured product leaves a good margin of profit.

ELECTRIC POWER IN BULK

By L. E.

EVERY year more and more attention is given to the supplying of power in bulk to manufacturers in rural districts, and a good deal of friction frequently arises between the large power companies and those municipalities who seek to develop their outlying districts. It may be said that up to the present this rural business has not been sought after in the British Isles as diligently as might have been the case. It is perhaps due to the fact that the possibilities of its development have not been estimated at full value, or possibly the parties interested have devoted more attention to the business which is nearer home and which is more immediately remunerative.

The cost of transmission is always a serious item when the sale of power in bulk is being considered. One company has increased the distances between supports gradually until they now have solid copper conductors operating with perfect satisfaction in spans of 250 feet. How much further they can extend is now a matter for experiment, but above 250 feet it would seem that local atmospheric conditions would have an important bearing on the subject.

Composite Conductors

Possibly copper-clad steel or other combination of metals may render it possible to increase that distance and so enable distribution to be carried out at a less cost per mile. Steel or reinforced concrete posts which are now being used in some localities may eventually do much to solve the support problem, for the simple reason that the maintenance of poles is a considerable item where the poles form a large proportion of the invested capital. Insulated copper is, of course, out of the question for rural work, as its increased weight shortens the spans, thereby raising the cost of supports, and the insulation neither adds any factor of safety nor decreases the cost of the supporting insulators.

There is some divergence of opinion as to the voltage which is best adapted for rural district supply and also as to the scheme of transformer connections which it is best to adopt as a standard. In the majority of cases 110 volts can be used for single, and 220 volts for polyphase work, as this perhaps offers the most flexibility of any scheme of secondary voltages. On the primary side may be used delta connected three wire 6,600 volts, and 2,200 volt systems.

A Desirable Circuit

There is of course much to be said in favor of 4,000 volt or 11,000 volt, star connected, earthed neutral primary circuit for rural work, as according to A. S. Hall, who has had a great deal of experience, it has the advantage of fewer earths being necessary, thereby lowering earthing cost, and a further advantage of enabling the circuit to be cut out entirely by an automatic switch in case any of the three wires should be earthed, whereas the delta connected three

wire primary will sometimes operate with one wire down. An increase of voltage is possible, with a resultant lower copper cost, and a single wire can be run to handle singe phase distribution transformers using earth return. Further, if any earth fault should develop it will be on the high-voltage side, which is the voltage being earthed against, and by earthing the secondary also the consumer is rendered doubly safe.

A plan which is sometimes followed, and which has saved considerable first cost, has been the banking of transformers in multiple, on both primary and secondary sides. This is not good practice in town work, but the objections are not so apparent in rural distribution and there is a decided saving in both transformer and copper on account of being able to use larger transformer units, and so take full advantage of the diversity factor of grouped consumers.

ELECTRIC LOCOMOTIVES MAY SUPERSEDE STEAM

Actual want of any commodity provides the most direct appeal possible for its conservation. The use of electricity, instead of steam, on those portions of Canada's railways adjacent to waterpowers would materially reduce our dependence on the United States for coal. In 1916, the railways of Canada used 8,995,000 tons of coal, or about 61 per cent. of our total production. A writer in "Conservation" remarks that the increased price of coal may soon compel us to use hydro-electric energy extensively as a railway motive power.

Certain American railway companies have carried out extensive experiments in electrification within the past two years and many of the results are of more than ordinary interest. On its Rocky Mountain division, the Chicago, Milwaukee & St. Paul replaced its steam locomotives by electric. Electricity is decidely superior to steam in operating efficiency, especially in cold weather. Electric power made it possible to operate more trains over the same tracks and that, without the need for "helper" locomotives. Again, there was a great saving in terminal and round-house facilities, and the rolling stock was not subjected to as much wear and tear as when steam was used. This latter fact was largely due to the superior braking qualities of electric-drawn trains. Air brakes were not used on grades, except in cases of emergency. In fact, it was found that as much as 11.3 per cent. of the power consumed during the period of the test was generated by the trains themselves on the down grades. The experiment was so satisfactory that the company has decided to instal electric equipment on its Cascade division as well.

In a region so lacking in coal and so rich in water-power as is Central Canada, we may expect that, in time, the increase in the cost of coal will, in favorable situations, induce the electrification of part of our steam railway mileage. If the coal now consumed by railway locomotives could be turned to other productive uses, an important step would be taken in making Canada more independent of the American coal market. Concurrently with that advantage, the country's trade balance would be considerably improved.

THE LEAD ACCUMULATOR AS A FACTOR IN TRANSPORTATION

By C. T.

IT is a rather surprising fact that the lead accumulator, as a source of motive power for electric pleasure vehicles, trucks, factory trucks, etc., has not become more general, considering the number of good sound business reasons in favor of its use in such applications. A little study of the accumulator itself will enlighten the reader on the main conditions retarding its adoption.

Early Forms

The "box of power," which Lord Kelvin, then Sir William Thompson, was so enthusiastic about, when he received it from Paris, had a great many serious defects. It was the first of the lead accumulators, in which the oxides were pasted on the lead plates, instead of being formed on them by the electric current, in the expensive way that N. Plante had adopted. It was followed a very large number of other forms of pasted plates, all of which were subject to the same faults; the paste was liable to chip off, and the plates themselves tended to bend towards each other, thus short circuiting the cell and running it down. Then numerous forms of grids were adopted, all designed with pockets to contain the oxides, so as to prevent them chipping off. The trouble with these was the fact that the oxides change in volume, or tried to do so, very considerably, in the process of charge and discharge, because of small pieces of the oxides being forced out of the grids and hence short circuit followed sooner or later. The pure lead grids also were subject to the same trouble as the lead plates as they tended to buckle and bend towards each other, thus giving better chances for small chips of the oxide to lodge between them. The oxides which were pushed out of the grids also tended to build up a bridge at the bottom of the containing jars, thus short circuiting the plates, when the bridge was complete.

Improved Types

Steady continuous work of 30 years has gradually eliminated the major of these troubles; the oxides do not as readily come out of their grids, and when they do they are prevented from short circuiting the cells by perforated separators, and by providing the plates with feet, causing them to stand well above the bottoms of the jars.

But after all trouble is only overcome by continual care, periodical testing, and continual charging. In the process of both charging and discharging the lead accumulator, sulphate of lead is formed. During charge, if the operation is properly carried out, the sulphate is all converted into oxides; but if not, some sulphate remains, interfering with the working of the cell as explained below. In the process of discharging, the formation of sulphate goes on more or less continuously. Sulphate of lead is, to all intents and purposes, an insulator in the position it occupies in the lead accumulator. It also tends to break the circuit, to break the connection between the electrolyte and the lead grid. If some lead sulphate is allowed to remain when charging is complete, it practically screens the portion of the lead plate upon which it is formed, from the action of the current, the resistance of the cell being higher in consequence, and its output less. If the discharge of the cell is allowed to continue indefinitely, a screen of sulphate is gradually built up all over the lead grid, which completely puts the cell out of action.

Care of Cell

It is standard practice now to not discharge a cell below a pressure of 1.8 volts, and 1.85 volts is better; 2 volts being the initial pressure directly after charging is completed. The lower the pressure to which a cell is allowed to fall, the greater is the difficulty in restoring it to its normal working condition. As long as the discharge has not gone too far, and the pressure has not fallen too low, the cell can be restored by prolonged re-charging, sometimes with an occasional discharge. But the restoration is affected at the cost of the lead grids themselves.

The improvements in the lead accumulator have been very much quickened by the advent of a rival in the form of the alkali accumulator. Salts of nickel, and iron are employed, and the whole thing is constructed in a very much superior manner from mechanical point of view. The plates in the alkali accumulator are of steel plated with nickel; and the active materials are carried in perforated boxes made of the same material, the boxes being held in the steel plates in such a manner that there will be hardly any of the troubles that arose with the early forms of lead accumulator. The alkali accumulator furnishes a much lower pressure than the lead accumulator, 1.2 volts per cell, as against the two volts of the lead accumulator, but it is claimed that a smaller weight of cells is required to perform a given work.

MEANS OF PRODUCING HEAT FROM ELECTRICITY

THERE are two ways of producing heat from electric energy—by means of resistance and by means of an arc—and heat can be produced for use by either of these methods from direct or alternating currents, single or polyphase and at any commercial voltage. Hence, practically all heating devices in the market can be

operated from any available source of current. Of these two methods, that of producing heat by means of resistance (aptly termed the "Joulean Effect" since it is based on Joule's Law) is almost universally employed; about the only exception is that of the use of the arc in arc welding and arc furnaces.

Alternating Current

Moreover, due to prevalence of alternating-current supply throughout the country as well as its greater flexibility and efficiency when used over the wide range of voltages required by the various processes of application, alternating current is used in the great majority of cases. The use of the transformer with its many available taps makes possible the attainment of varying temperatures with an ease and efficiency that cannot be approached by the use of direct current, and as the heating unit load is practically noninductive and can be used in polyphase as well as single-phase circuits, the use of alternating curent for this work gives a unity power factor in almost every case and possesses many advantages over direct current. For instance, in order to obtain the low voltage used in spot welding from a direct-current supply, it would be necessary to employ a rheostat in connection with a specially wound low-voltage generator with the attendant large losses, while by the use of alternating current these voltages are readily obtained from practically any commercial supply circuit by means of the transformer.

One of the many advantages of electric heat is that it is susceptible of graduated and automatic control as to localization, time and temperature, to an extent and nicety impossible with any method of combustion. This is true whether the control be by hand or automatic, although automatic control permits of greater refinement than does hand control.

Control Methods

Varying heats, high, low and intermediate, are obtained with hand control by switching devices which connect the heating units or groups of units in series, in parellel or in series-parallel, much in the same manner as a four-motor street-railway equipment is handled, while if an alternating current is used, this same effect is also obtained by use of the delta-Y connection with constant voltage on the supply.

These different heats occur in certain well-defined and distinct steps according to the wattage produced by the various connections and grouping of the heating units, although in cases of small current demand, gradations between these steps can be obtained by means of a rheostat in the case of direct-current supply, and by varying the voltage on the secondary side of the transformer when alternating current is used.

In carrying on the various processes of industrial heating there is always a certain definite temperature that will produce the best results in the shortest time; which is best suited to any particular phase of the process, and it is the ability of electrically controlled units to not only meet and maintain this specific temperature to a nicety, but also to vary within a fraction of a degree with the temperature requirements of the various phases of the process, that makes the electric control stand out as superior to that employed by any method of combustion heating.—Society for Electric Development Bulletin.

ELECTRICAL NOTES

Watt Meter Reading.—In measuring the power on a three-phase power circuit withone single phase watt-hour meter, how should the readings be added up to get the total amount of power consumed by a motor?

Answer.—The arrangements can be made to vary, dependent upon whether it is required to make the reading once or for permanent use. To consider the first condition, number the three line wires as 1, 2, and 3. Connect the current coil of the meter in any one of the wires, say, No. 1. One end of the potential coil is already attached within the meter. Connect the other end to one of the other two wires, say, to No. 2. When the motor is running, take the readings by counting the number of revolutions of the disc in a given time and interpret this in watts according to the regular rules for reading meters. Now stop the motor and connect the current coil of the meter in main No. 3, leaving the potential coil unchanged. Take the readings under these conditions. If the motor is running "free" the chances are that in one of the two connections the meter disc will turn slowly backwards, and in the other positions it will turn faster forwards. In case these two directions are realized, the backward turns are to be subtracted from the forward. It will always be the case when the power factor is less than 50 per cent. When the power factor is just 50 per cent. the meter that turned backwards will completely stop. In this case the entire true power is recorded by the other meter. When the power factor is greater than 50 per cent. both meters will turn in the forward direction, but at different rates, and the sum of the two readings is to be taken. For the second condition—for permanent connections—you will need to set up an artificial "Y," say, for an approximate determination, by connecting incandescent lamps in series. Just the size and number to use would depend upon your particular voltage. The three ends represented by the Y are to be attached to the main line wires. The middle point of the Y serves for connection to the required terminal of the potential coil of the meter, the current coil being connected into any one of the mains. The meter will now record one-third of the total power, so the readings are to be multiplied by 3. An error in this method of determination is due to the fact that the potential coil has now but about three-fourths of the voltage impressed upon it as that for which the instrument was calibrated and it may run too slowly.—R. B.

* * *

Starting Box Connections.—A text book which I have on electricity shows the connections for a starting box on a direct current shunt motor, with the release magnet in series with the shunt field, but while making a repair on a starter for a 20 h.p. shunt motor in the plant where I work I noticed that the electro magnet was independently connected across the line and not in the field circuit. Would not the method given in the book be the correct way to protect the motor from dangerous speed if the field circuit was broken?

Answer.—A large number of present-day motors are designed for adjustable speed by shunt field control. The range of the shunt field current is so great that it is practically impossible to design a no-voltage release coil to go in series with the shunt field and work over this range. A coil in series with the field must be designed for a specified magnetizing current for the particular motor on which it is to be used, and this varies in differently designed motors of the same h.p. rating. In order to avoid these difficulties the coil is put across the line. It does not afford any protection against open circuit in the shunt field, this contingency being taken care of by the overload circuit-breakers or fuses in the line.—J. M. S.

Meaning of K.V.A.—Kindly explain what is meant by the following on a name-plate: 200 k.v.a, 5,000 alternations, single phase, 550-volt alternator? I wish to know the meaning of a kilovolt ampere; how it is obtained in this case, and its use in stating the rating of electrical apparatus.

Answer.—With direct-current the product of the number of volts by amperes gives the watts, and 1,000 watts, of course, is a kilowatt. The same is true of alternators when the circuit is simply straight resistance with no inductance. Such instances would be typified by incandescent lamp loads, furnaces, and the like. When motors, transformers, etc., are used, the current lags behind the volts in phase, and the instantaneous true power is not the simple product, but a number less than that; therefore, the kilowatts are less than the kilovolt amperes. As it is usually desired to keep track of the current capacity of the machine, the latter expression is the more useful. The term "alternations" is usually employed to give the number of single reversals per minute, a cycle being two complete alternations, and cycles per second, which is the more usual designation, being the number of double reversals per second. Thus, 5,000 alternations would then be regarded as $\frac{5,000}{120} =$ 42 cycles per second. The 200 k.v.a., 500-volt machine would then have a current capacity of 363 amperes, but the character of the load would determine whether 200 k.w. or less was in the circuit.—W. N. R.

WILL INVESTIGATE GAS PROBLEM

THE serious condition existing throughout South-Western Ontario as a result of the shortage of natural gas is to be investigated at once by the Ontario Railway and Municipal Board. The board will be asked to enquire into a number of things that are causing a great deal of ill-feeling and controversy in the district. On one hand it is charged that the producing companies are not producing up to capacity in order to further plans for getting new contracts at higher rates. Another complaint is that while some municipalities are getting an adequate supply of gas others, in which contract prices are lower, are going without.

PUMPS WANTED IN FRANCE

THE "Official Bulletin" of the United States Government announces that the following cablegram has just been received from the Paris headquarters of the American Red Cross:—

"'Send us pumps,' is an appeal to-day from a Red Cross delegate in the devastated area. The retreating Germans left little untouched there last spring. Spokes were cut from wheels of farm carts, orchards were felled, farmhouses wrecked. In many cases pumps were destroyed, wells filled with rubbish and polluted.

"Of the few men and women who have managed to filter back to live in the one good corner of their wrecked buildings, to clear the fields of barbed wire and try to till them, none dares drink from the old wells which they had depended on all their lives unless they bear a sign reading 'Good water,' to show that they have been purified.

"To these safe wells people come from far and near with their jugs and pails. To make their already difficult life a little easier and to make it possible for more of them to come back to their devastated fields—all they have—as soon as pumps can be brought, ten will be sent to fill the need for them in this district. It is a real though slight contribution to the giant task of reconstruction."

PULPWOOD REFORESTRY

THAT the greater portion of the cut-over pulpwood lands of Canada will take from 30 to 100 years to reforest themselves instead of about 20 years, as lumbermen have supposed, is the statement made by Dr. C. D. Howe, of the Faculty of Forestry, University of Toronto, to the Commission of Conservation.

Of special significance, in view of a possibility of the diminishing coal resources of the United States soon forcing Canadian railways to use hydro-electric energy for traction purposes, was the address of S. T. Dodd, traction expert of the General Electric Co., Schenectady, N.Y. He fully described the electrified western section of the Chicago, Milwaukee and St. Paul Railway, which covers a distance of 440 miles, and has found electric traction to be considerably cheaper than steam.

EFFICIENCY INSTRUMENTS FOR SMALL BOILER PLANTS

IT is the rule, rather than the excepiton, for designers and managers of modern, large size steam power plants, to spare neither pains nor expense in providing first class, labor saving, economy producing devices throughout the installation, knowing well, from past experience, that the saving effected by their use will more than repay that first cost involved.

How, then, is one to account for the pronounced lack of interes, which is characteristic of owners and managers of small isolated-boiler plants, in securing more efficient operation from their power units by instaling a few of the common, money-saving appliances? If this atttitude is due to a belief that the cost of such devices renders their use prohibitive except for the large stations, it is wrong. If it is the result of indifference, it is criminal. When it is considered that while the actual waste in fuel in any individual station may not be inordinately large, the sum of these preventable wastes taken from the thousands of small capacity plants, must represent in the aggregrate many thousand tons of coal per year. This is equivalent to squandering the rapidly dwindling coal resources of the country. Now, more then ever before, when the scarcity of fuel has become so acute as to constitute a grave national crisis, it behooves every steam producer to get the most out of every pound of coal, and this can only be accomplished by tackling the problem in a scientific way.

It is suggested by C. T. Baker, in a recent issue of "Industrial Management," that the small plant should be managed and operated along scientific lines as well as the big ones, but in carrying out the policy too much should not be attempted at once. Progress should be made a step at a time adding some new piece of apparatus such as a CO^2 recorder, flue gas thermometer, draft gauge, etc., as soon as circumstances permit, and making it a point to see that the operating force is thoroughly instructed in the use of such apparatus as fast as it is installed.

If the management and engineer of the small and medium sized plant will look over their apparatus carefully, and analyze their boiler plant operation fully, they will find many ways to effect a substantial saving at a relatively small outlay of money. In some instances, boiler efficiency can be so materially increased as to permit the shutting down of one or more boilers for a part of the day or night and may result in some cases in saving a considerable outlay of money for additional boilers, where it has been supposed that the boilers were overloaded.

ALCOHOL AS AN ENGINE FUEL

THE suitability of alcohol for generating power in the internal combustion engine has been sufficiently established by exact tests and by practical experience of alcohol motors for general purposes. The conclusion thus drawn is that, although the calorific value of alcohol is little more than half that of gasoline, the efficiency per brake horse-power is from 28 to 31 per cent. compared with that of 16 to 20 per cent. for gasoline. The higher efficiency of alcohol is due to severals factors, namely:—The volume of air required for complete combustion is about one-third of that required by gasoline, thus reducing the waste heat in the exhaust. This smaller dilution with air ensures more perfect admixture before the explosion and consequently favors complete combustion. The mixture can be subjected to a pressure of 200 lb. per square inch in the cylinder without spontaneous ignition; the saftey limit for gasoline is 80 lb. Mixtures of alcohol vapour and air containing from 4 to 13.6 per cent. alcohol are all explosive, whereas the explosive range of gasoline is from 2 to 5 per cent; thus requiring more exact adjustment of gasoline and air in the cylinder. The exhaust from the alcohol engine is smokeless and odorless and the products of combustion do not clog the cylinder valves.

CARBON BRIQUETTES WOULD SAVE MONEY

TO save from 45 cents to $2.50 per ton is a possibility for the anthracite coal users of the Prairie Provinces. In 1916, Canada imported 4,570,000 tons of anthracite coal, nearly all of which was used for domestic purposes. Of this, about 400,000 tons were shipped to destinations in Manitoba and west thereof for domestic use. As the eastern portion of Saskatchewan forms the competitive area between supplies of United States coal on the one hand and the high grade bituminous coal of the Rocky Mountains on the other, the cost of coal in that portion of the province is high.

An investigation undertaken by the Commission of Conservation in co-operation with the Advisory Council for Scientific Research shows the economic possibility of manufacturing a high-grade fuel from the lignites of Saskatchewan. The results are published in the pamphlet "Carbonizing and Briquetting of Lignites." Carbonized lignite briquettes are stated to be practically equal in heating value to anthracite coal. They will, therefore, stand comparison very closely on the basis of cost. An examination of the accompanying table will show that the difference in favour of briquettes as compared with anthracite coal varies from 45 cents per ton at Portage la Prairie to $2.50 per ton at Moose Jaw. This allows a profit of $1.00 per ton to the producing plant having a capacity of 30,000 tons per annum. With a capital cost of $400,000, this would return 7½ per cent. on the investment. The lower price of carbonized briquettes would mean a large saving to consumers in western Manitoba and Saskatchewan and a plant such as that referred to would save some $225,000 to the country annually which is now being paid ti American coal producers.

Steam and Its Generation

EFFECT OF BRICK ARCH ON SMOKE ABATEMENT*

By J. T. Anthony**

THE hard service and almost continuous variation in load under which locomotive boilers are operated renders the results submitted by the author of more than passing interest, and much of the data given will be found capable of immediate and profitable application to many stationary boilers.

The Master Mechanics' Proceedings of 1913 contains the report of the smoke committee appointed by the General Managers' Association of Chicago, which states that "while running, the brick arch is capable of making a 50-per cent. reduction in smoke, irrespective of steam jets."

The tests upon which this statement was based were run with Penn gas coal of the following composition: Fixed carbon, 57.74 per cent.; volatile matter, 34.07 per cent.; moisture, 1.05 per cent.; ash, 7.14 per cent.; B.t.u. per lb. of dry coal, 14,520. The smoke reduction of 50 per cent. was accompanied by an increase in evaporation of 8.6 per cent. due to the arch.

Results With Brick Arch

The Chicago Smoke Commission (of which Dean Goss was chief engineer) made extensive tests, with and without the arch. They found the brick arch to achieve the following: Decreases the average density of visible smoke emissions, 33 per cent.; decreases the total average quantity of cinders and fuel dust emitted in smoke, 25 per cent.; decreases the amount of carbon contained in cinders and fuel dust per ton of coal consumed, 24 per cent.; decreases the amount of ash contained in same, 28 per cent.; decreases the volume of air intermingled with gases of combustion discharged through stack, 15 per cent.; increases the volume of CO_2 discharged through stack, 6 per cent.; decreases the volume of CO discharged through stack, 10 per cent.; increases evaporation per pound of coal, 7 per cent.

These Chicago tests were run with coal from McCoupin County, Illinois, of the following composition: Fixed carbon, 37.47 per cent.; volatile matter, 38.41 per cent.; moisture, 9.89 per cent.; ash, 12.23 per cent.; B.t.u. per lb. of dry coal, 12,884. Both tests were run with a locomotive having a narrow firebox, 40 in. wide by 106 in. long, with 29 sq. ft. of grate area. The air inlet through ashpan was 5.7 sq. ft., or 20 per cent. of the grate area. The arch was 66 in. long and was supported on two arch tubes.

The final conclusions of the foregoing test report also state that "the presence of the brick arch in the locomotive firebox increases efficiency and decreases fuel consumption, decreases the loss of heat units in smoke and ash discharged and reduces the visible smoke. The use of incorrect methods of firing, as indicated by the results of tests in which inexperienced firemen were employed, reduces efficiency, increases fuel consumption and fuel losses and increases smoke discharges."

Smoke Reduction

Tests recently conducted on a Mikado-type locomotive shows smoke reductions varying from 50 per cent. at low and medium rates of firing to 31 per cent. at high rates. The locomotive was hand-fired, using high-volatile Pennsylvania gas coal screened over a 1¼-in. mesh screen; the coal having the following composition: Fixed carbon, 54 per cent.; volatile matter, 31 per cent.; moisture, 0.92 per cent.; ash, 14.08 per cent.; B.t.u. per lb. of dry coal, 13,088. This locomotive had 70 sq. ft. of grate area; a barrel combustion chamber 42 in. long; a 76-in. arch supported on four 3-in. arch tubes; an air opening through ashpan of 7.80 sq. ft. (or 11 per cent. of the grate area) and air openings in grate of 20.21 sq. ft. (or 28.8 per cent. of the grate area.)

In these tests the increase in evaporation, due to the arch, varied from 8½ to 15½ per cent. These three tests are probably the most thorough and reliable that have ever been conducted for the specific purpose of determining the effect of a brick arch on locomotive smoke abatement; and the test results—a reduction in smoke of from 30 to 50 per cent.—are corroborated by the practical experience of railroad men throughout the country. The principal measures taken by railways to-day to meet smoke ordinances consist of issuing firing instructions and equipping locomotives with brick arches.

The formation of smoke is due primarily to the decomposition of the volatile hydrocarbons contained in all bituminous, semibituminous and lignitic coals; though the presence of coal dust that is fed into the firebox, caught up by the draft and whirled out through the flues unburned, adds to the smoke emissions.

As the name indicates, the volatile hydrocarbons are compounds of carbon and hydrogen and are of a very complex character. The heavier compounds are driven off in the form of tar, in a semi-liquid or solid state; while the lighter hydrocarbons are driven off in a gaseous state. The distillation begins at a temperture around 40 deg. F. and is completed at a temperature of 1,600 deg. F. The decomposition of the volatile matter by the action of heat takes place readily at temperatures above 1,400 deg. F.

The exact composition of the hydrocarbons when first distilled from the coal at the different temperatures is not known, as they break down so readily under the influence of heat and are so unstable that it is impossible to collect samples for analysis. The indications are, however, that the heavy hydrocarbons, when first driven off, contain (by weight) about 85 per cent. carbon, 10 per cent, hydrogen and 5 per cent. oxygen. Under the influence of heat, these hydrocarbons break down into carbon, hydrogen, oxygen, lighter hydrocarbons of the methane (CH^4) series and lighter unsaturated hydrocarbons.

The hydrogen, a colorless gas, is highly inflammable and burns readily if there is an oxygen supply above the fuel bed. The lighter hydrocarbons also burn readily if the oxygen supply is sufficient. If it is insufficient, the hydrocarbon is broken down by the heat into carbon and hydrogen, the hydrogen either combining with the oxygen that may be present, to form water, or escaping into the flues unburned.

Soot Formation

Carbon does not exist in a gaseous state at temperatures with which we are familiar in furnace practice; so that when the vrious hydrocarbons are decomposed, the carbon is precipitated as a solid particle in the form of soot; and these incandescent particles floating in the flame give it the luminous color.

The particle of soot (resulting from the breaking down of the hydrocarbons) is well on its way to the flues at the instant of its formation. As was previously noted, it is not brought into violent mechanical contact with a supply of oxygen, but floats along in an atmosphere that has been robbed of much of its oxygen in passing through the fuel bed. The temperatures prevailing in the upper part of the firebox are sufficiently high, generally, to insure ignition and combustion; but under ordinary conditions the

*Abstract of paper read at convention of Smoke Prevention Association, Columbus, Ohio, September, 1917.

**American Arch Co., New York City.

time available for combustion varies from 1 5 to 1 10 of a second, and this is insufficient.

The small quantity of oxygen above the fuel bed; the difficulty of bringing the oxygen in contact with the soot, due to ineffective mixing of the interference of the large volumes of inert and noncombustile gases; and the short time available for combustion, make the burning of soot and the elimination of smoke in locomotive operation a rather difficult matter.

With the conditions that prevail in the locomotive firebox, it is easier to prevent the formation of soot (or smoke) than to burn it when once formed. The precipitation of soot can be prevented by having an excess of heated air (or oxygen) above the fuel bed and bringing this heated oxygen in intimate contact with the volatile hydrocarbons at the instant they are distilled off.

Research work done by the United States Bureau of Mines indicates that the hydrocarbons are decomposed when they have traveled but a few inches from the top of the fuel bed; and if the precipitation of carbon is to be prevented, the air (or oxygen) must be introduced at the top of the fuel bed and intimately mixed with the issuing hydrocarbons.

Arch Mixes Gases

The chief function of the brick arch in abating smoke is that of a gas mixer. By baffling and compelling all the gases to pass through a relatively restricted area above the arch, an intimate mixture of the volatile combustible with the oxygen is insured. While the mixing of the gases at the end of the arch does not take place soon enough to eliminate smoke entirely it has the effect of reducing the smoke emissions, as shown by the tests quoted.

With a firebox without an arch with a characteristic fire—that is, with a bank of green coal under the fire-door, the fire gradually thinning down toward the front end of the grate, where the draft has possibly pulled a hole in it—the bank of green coal under the door is expelling large volumes of rich hydrocarbons, which, passing up along the top zone of the firebox, are decomposed by the heat, causing the formation of soot, which either escapes at the front end as smoke, or is deposited on the heating surfaces to retard the flow of heat. At the same time a large excess of air is rushing through the thin portion of the fire on the front of the grate and is passing directly into the lower flues, without in any way aiding the combustion of the hydrocarbons being distilled in the back of the box, and very often causing flue leaks or failures.

Such conditions are not at all uncommon in locomotive fireboxes unequipped with the arch. Front-end gas analyses often show a large excess of oxygen, due to the blast of air through lower flues, in combination with high carbon-monoxide, hydrogen and hydrocarbon contents, due to incomplete combustion of the volatile hydrocarbons arising from [illegible] under the door.

Where the arch is provided, any excess air coming through the thin portion of the fire on the front of the grates is heated up, deflected and forced back over the end of the arch, where it is mixed with the gaseous combustibles rising from the green coal under the door. With the ordinary type of firebox, the combustion chamber space and the flameway are insufficient to give all the particles of soot and combustible gas time to burn before reaching the flue sheet; but such a mixing as the arch affords results in a material reduction of the smoke, and under moderate rates of firing will result in almost complete combustion of the combustible gases.

Green Fire Conditions

The arch, however, is not sufficient to eliminate smoke when the method of firing here described is followed. A heavy bank of green coal restricts the flow of air at the point where it is most needed and at the time when it is most needed, with the result that most of the hydrocarbons are broken down and the carbon precipitated before being brought into contact with the oxygen entering through the front grates.

A similar condition prevails where the banks cause a restricted flow of air through the fuel bed at the points where the maximum distillation of hydrocarbons is taking place.

A light, level fire should be carried if smoke is to be reduced to the minimum. With the fuel bed in this condition and a "scatter" type of firing being followed, a uniform air supply is obtained throughout the fuel bed, as well as a uniform distillation of the hydrocarbons. This facilitates the mixture of the oxygen and the hydrocarbons from the time they leave the top of the fuel bed, the arch merchanically accelerating this mixture.

Some authorities state that the decomposition of the hydrocarbons is caused by heating them up with an insufficient air supply and then bringing them in contact with the cooler heating surfaces or a draft of cold air. While later evidence tends to prove that this decomposition is caused entirely by heat, shafts of cold air through the firebox are objectionable, both from the viewpoint of combustion and that of boiler maintenance.

Where the arch is used, shafts of cold air entering through the fire-door and holes in the fire are made to mix and mingle with the products of combustion and combustible gases, thereby aiding combustion; and being brought to the temperature of the other gases are prevented from causing uneven temperatures or violent fluctuations at the flue sheet.

Intelligent Firing also Needed

It is evident from the foregoing that the arch is not in itself sufficient to prevent smoke. Intelligent firing is also necessary. Smokeless firing and intelligent firing are almost synonymous, although there are conditions under which smokeless firing is impossible, regardless of the care and intelligence exercised by the firemen.

In some quarters, however, there has been prevalent an idea that smoke was mainly a nuisance and that the emission of dark clouds of smoke did not signify any appreciable heat loss. As a matter of fact, the emission of smoke not only indicates bad furnace conditions, but in many cases the soot and tar escaping as smoke may contain from 10 to 15 per cent. of the heat value of the coal; and this will account from a considerable portion of our "unaccounted-for" heat losses. Tests conducted by the United States Bureau of Mines (set forth in Technical Paper 137) showed that when burning Penn gas coal as much as 32 per cent. of the combustible rising from the fuel bed is accounted for in the soot and tar which is the source of smoke.

In his original paper the author goes ion to show the effects of the arch in different types of locomotive fireboxes and to suggest improvements in design. Several illustrations are also shown. Written discussion of Mr. Anthony's paper was presented by F. S. Deveny, of the Baltimore & Ohio R.R., Chicago, in which he corroborated Mr. Anthony and gave data on the maintenance of arches.

GAS FIRING AND REGENERATIVE SETTINGS

By T. J.

IN the earlier days of gas firing, as applied to retort settings, there were some rather vague ideas current as to the economy just effected. The saving of fuel consumption and the higher working temperatures attained in the retorts were often too hurriedly attributed to the recovery of waste heat. Waste heat is, of course, recovered, and returned to the setting in the preheated secondary air, but all the advantage does not lie merely with this recovery.

The advantages of gas firing as ordinarily practised are chiefly in three directions:—(1) The application of heat. High temperatures are generated in close proximity to the retort, and not as with direct firing at a considerable distance away, where much of the heat applied is in the form of much cooler and rapidly cooling convection currents of gaseous products. The study of flames may be applied with advantage to the question of gas firing of retorts, which is really a question of the application of flames. (2). The regulation of air. This can be accomplished to a very fine point so as to avoid the drop of available temperature due to the admixture of a large excess of air. (3). Regeneration or recuperation. Much heat is in waste products, i.e., gaseous products of combustion (mixed with air), which have passed the retorts and are on their way to the chimney. Any of the contained heat that can be transferred to the incoming air (usually the secondary air) is so much pure gain.

In Europe regeneration and recuperation of heat are used pretty much as interchangeable terms. In America recuperation is applied to the process by which (as in retort settings) the heat of the waste gases is transmitted through the walls of a flue and is given up to the air in an adjoining flue, while regenera-

tion is there chiefly confined to the recovery of heat from heated chequer work over which the hot waste gases are first passed, and then by a change-over valve the incoming cold air is led over the same chequer work. Regeneration in this sense was tried on gas works, but its use was not long continued, though the same arrangement is successfully used on some coke-ovens, notably the Simon-Carves type.

Recovering Waste Heat

It is often too rashly assumed that all the heat taken to the combustion chamber by the secondary air of an ordinary retort is this recovered waste heat. It is usefully applied heat, but not necessarily all waste heat. Some of it may be initial heat. In cases where the secondary air travels are placed between the waste gas flues and the furnace, some of the heat in that air will undoubtedly be derived from the furnace. As the air is ceaselessly passing through these flues, and thus tending to cool them, this constitutes a drain upon the heat resources around the flues, and thus will certainly withdraw some of the furnace heat. Whether this procedure may be right or wrong may be open to discussion.

It is all to the good to get the secondary air as hot as possible; but no mistake should be made by considering the heat it withdraws from the neighboring furnace as recovered waste heat. It is abstracted initial heat, and its loss tends either to increase the fuel consumption or to lower the temperature of the producer gas. It may seem unnecessary to labor or even to mention the point, but the heat that can be produced from a given weight of a given coke is fixed and unalterable, whether the coke is burning direct to the carbon dioxide, as in direct firing, or first to the monoxide and then to the dioxide, as in gas firing. Still the idea lurks around in some minds that gas firing actually produces more heat from the fuel.

What gas firing really does is to transfer much of the heat production from the generator to the actual setting some 70 per cent. of it. In the same way the use of water on the fire bars, which when vaporized and passed through the furnace generates some water gas, does not furnish any new source of heat. Whatever heat is given out by its combustion exactly balances the heat abstracted in its formation. All that is gained in a thermal sense is the transference of heat from the lower part of the fire, where a high temperature favors the formation of clinker, to a high zone where it is more useful and less likely to entail harmful secondary effects, such as fusing the ash into clinkers.

STEAM TURBINES v. DIESEL ENGINES

IT is sometimes remarked as a curious fact that the Diesel engine, whose fuel is oil, finds little favor in the oil regions of the United States. The explanation is, of course, that where fuel is cheap, the most economical type of power plant is one which entails the lowest first cost and the lowest maintenance charges rather than one which can show the highest thermal efficiency. This is one particular instance of the way in which the various factors which determine the choice of a prime mover vary according to the locality and to the conditions of each separate case. Another consideration, which may in extreme cases become decisive, is the load factor of the plant. Obviously, if a power plant is to work only intermittently, the extra capital charges on a highly efficient plant may easily outweigh the saving on the fuel due to the greater efficiency.

The cost of water is another factor in the equation. As between the Diesel engine and the steam turbine scarcity of water will sometimes turn the scale in favor of the Diesel, even when other weighty factors are against it, since about twelve times as much water is required for condensing purposes with steel turbines under general conditions as is needed for jacket cooling with a two-stroke Diesel engine, while four-stroke engines need only one-twentieth the water. In a paper read before the American Institute of Mining Engineers, Herbert Haas sums up concisely the economic considerations governing the choice between steam turbines and the Diesel engine in Western America. Where fuel is dear and the load factor is high, the Diesel engine has the pull; where contrary conditions exist the steam turbines come out the best except where the instant readiness of the Diesel engine gives it preference, and installation cost is of secondary importance. Here it is necessary to balance the cost of keeping boilers under steam continuously against the difference of interest charges of steam turbine and Diesel engine plants. For power plants erected at the source of the fuel either on the oilfields or at the coal mines prime movers will be selected costing least to instal, i.e., steam turbines, since fuel expenditure will weigh less than interest and redemption charges.

In many cases combination plants using Diesel engines for supplying power continuously against the constant main load, and steam turbines for furnishing periodically occurring peaks by the same use of high duty boilers with large water and steam spaces, capable of being forced when necessary, will prove most profitable. Up to capacities of 1,000 horse-power steam turbines can compete with Diesel engines only in special cases, such as supplying exhaust steam for heating purposes. For such small units, particularly for greatly varying loads, reciprocating steam engines are preferable. For larger plants than from 1,000 to 10,000 kw. capacity careful analysis must be made of the relative advantages of Diesel engines and turbines, a knowledge of the load factor, fuel prices, and water conditions being necessary. For power plants larger than 10,000 kw. using units from 6,000 kw. upward steam turbines have the preference, unless a combination of high load factor, high fuel cost and poor water conditions favor a Diesel plant.

WRECKING OF 50-TON AMMONIA COMPRESSOR

THE following particulars of an accident that wrecked a 50-ton amonnia compressor at St. Louis recently are of particular interest in view of the age of the machine, 25 years, which had presumably been free from previous mishap. The compressor was a single-acting machine of the double, vertical, Corliss-engine-driven type installed about 25 years ago. According to the facts as published in "Power," the accident appears to have resulted either from sticking of the discharge valve of the left-hand cylinder or from an accumulaltion of weak liquid ammonia in the suction piping.

The fact that the machine had been standing idle for several weeks, thus giving the slight percentage of water vapor in the ammonia gas ample time to gather in considerable bulk by precipitation in the pocket formed in the piping just outside the suction stop valve, supports the latter assumption. With the second or third discharge stroke of the left-hand piston a tremendous thump was heard, and the vertical frame upon which the cylinder rests, and which is forked front and rear to form four supporting columns at the base, snapped in three places, thus allowing the cylinder to be forced upward. The resulting strain on the 4-in. discharge piping caused a fracture of the sweep tee, which joined the branches from the two cylinders with the main discharge line.

Two oilers, who were standing on the upper gallery at the moment, leaped to the floor below, and besides the injuries thus sustained, were severely burned and partly blinded by the escaping ammonia. The machine is fitted with the customary by-passes for pumping out the cylinders and contiguous suction and discharge piping by means of one of the compressors in operation. The by-pass valves had been opened before the engine was started, and what was deemed ample time was allowed for cleaning the system of any liquid accumulations.

On account of the staying of the wrist-plate stud by means of hog-chains passing fore-and-aft along the face of the wrist-plate and thence diagonally to fastenings at the ends of the cylinder, the starting bar could not be used for the usual preliminary working of the engine valves by hand.

Hydro-Electric Development. — The development of hydro-electric power in Canada, and especially in the Provinces of Ontario and Quebec, during the last ten years, has been almost incredible. At the beginning of the work of the Ontario Hydro-Electric Commission, the late Premier, Sir James Whitney, stated the Commission would not require so much as 10,000 h.p. There is now, in round figures, an immediate demand for 300,000 h.p., and the demand cannot be satisfied.

COMBUSTION EXPERTS CO-OPERATE WITH MANUFACTURERS' ASSOCIATION

UNDER date of January 10 the Canadian Manufacturers' Association have issued circular letter No. 151 to Quebec, Ontario and Manitoba members, advising manufacturers that the following gentlemen, all well versed in the economics of combustion, may be freely consulted, without charge, by those who feel the need for expert advice in the solution of their fuel problems:

Alfred Balmfrith, chief engineer, McGill University, Montreal, Que.

Olaf E. Granberg, vice-president, Boiler Inspection and Insurance Company, 227 Board of Trade Building, Montreal, Que.

W. F. Grazes, chief engineer, Montreal Tramways Company, Montreal, Que.

James A. Milne, electrical and mechanical engineer, Works Department, City Hall, Toronto, Ont.

H. N. Roberts, president, Boiler Inspection and Insurance Company, Continental Life Building, Toronto, Ont.

J. O. B. Latour, chief engineer, General Accident Assurance Company of Canada, Continental Life Building, Toronto, Ont.

A. L. G. Taylor, resident inspector, Boiler Inspection and Insurance Company, Electric Railway Chambers, Winnipeg, Man.

The following series of "Dont's" has been drafted by Mr. Latour and the association executives request that recipients pass it on at once to their engine room staff in order that they may get full benefit from the timely advice to firemen and engineers:

All of these gentlemen have volunteered for the service from a sense of national duty. They cannot, of course, neglect their regular work, but as far as their time permits all of them will be glad to give their best help to manufacturers calling upon them.

USES OF COAL-TAR PRODUCTS

By O.C.

WOOD, when exposed to moisture or set in water, may decay through the action of different organisms or fungi, or it may be destroyed by insects. To prevent this the timber is soaked in some chemical which will act as a poison to such enemies. Mercuric chloride, copper sulphate, and zinc chloride are examples of suitable poisons, and of these the last named is widely used. They are, however, all soluble in water, and may be rather quickly washed out by rain, etc. Creasote oil, on the other hand, is an efficient preservative which is insoluble in water, and consequently is more permanent in its action. It gradually evaporates, but if a heavy oil be chosen, the rate of evaporation is very slow. Creosote oil is the most suitable material for timber preservation, and is most used in Canada. Coal tar, also insoluble in water, is often used, but its penetrating power is very small.

The wood to be preserved by creosote is put in iron tanks, which are then closed and evacuated; the heated oil is now run in and the wood allowed to remain immersed under pressure for some time to ensure the complete filling of the pores. The preservative, to be effective, should contain high-boiling oils; for general purposes not more than 50 per cent. of it should distil below more than 315c. But for wood paving blocks not more than 55 per cent. should distil below that temperature. Economy of creosote oil can be obtained by the use of an inferior oil, which would be mixed hot, in the proportion of 80 parts oil to 20 parts of coke-oven tar, the latter containing not more than 5 per cent. to 6 per cent. of free carbon. The penetration of such a mixture is not less than that of the creosote oil, if the time for which the timber is kept under pressure be slightly increased.

On the American continent the demand for creosote oil is much greater than the supply. In 1913 the United States consumed, for timber preservation, over 90 million gallons (Imperial) of the oil, and of this 62 per cent. was imported from Europe. Between 60 per cent. and 70 per cent. of the total quantity of oil consumed was used for the treatment of railway ties, some 25 million being thus treated. In Canada, 19 million cross ties are used annually, and only about 10 per cent. of these are creosoted; but even for this comparatively small number Canada does not produce sufficient creosote oil. If all the tar produced in gas and coke-oven works in Great Britain were distilled, the home supply of creosote oil would still be quite unequal to the demand, and tar distillers would therefore be certain of a sale for one of their most important products.

Raw tar is sometimes used in the making of roads, but it is better to employ the prepared or dehydrated tar. This is generally poured or sprayed on existing roads. In dry weather it serves to keep the surface free from dust, and in wet weather it protects the road material from the distinegrating effects of water. In the actual construction of roads, coal-tar pitch and asphalt are much used instead of tar. Coal-tar asphalt is made by mixing pitch with suitable quantities of creosote and anthracene oils; and although it cannot entirely replace the natural asphalt in street paving, it is a very good substitute. For making sidewalk, a mixture of coal-tar pitch and natural asphalt is often employed, sandy material being ground up with the mixture, which is then melted and mixed with gravel. The use of pitch, etc., in the making of roads is increasing rapidly, and even at the present time there is a good demand for this residual material from the distillation of coal-tar.

Other Products

Carbolic acid, another coal-tar product, in its pure crystallised state, is used for medicinal purposes as an antiseptic, etc., but it has a much wider application in the crude state for disinfectant purposes generally. The impure carbolic acid has a strong unpleasant smell. It becomes partially liquid on standing, and in this state is much used for disinfecting sewers, stables, etc. Various preparations of carbolic acid or other phenols are made to render the application of the disinfectant more convenient. The most important preparations are those in which the phenols are combined with soap; but carbolic-acid powders, which are mixtures of carbolic acid and lime, etc., are extensively used. Naphthalene sometimes replaces carbolic acid, as a disinfectant, being used in sick rooms, etc., and is often preferable to carbolic acid for the dressing of wounds.

FUEL SAVING "DON'TS"

By J. O. B. Latour, Chief Engineer, General Accident Assurance Co., of Canada Toronto, Can.

1. DON'T fill the furnace with the intention that there will be no necessity for any additional fuel for the next two to four hours. This is quite a common practice with heating boilers, and with bituminous fuel results in very great waste.
2. DON'T regulate the draft by closing the ash pit door, but regulate it with a damper in the smoke flue or pipe between the boiler and the chimney. This also applies to any kind of furnace.
3. DON'T allow any cracks in the brick setting of the boilers, because cold air will enter through these cracks and absorb the heat that should have been transferred to the boiler.
4. DON'T permit the use of grates of any kind which are in bad condition. This will permit the unconsumed fuel to fall through to the ash pit and be shovelled out as ashes or waste.
5. DON'T use a grate that is larger than will permit the burning of at least 12 lbs. of coal per sq. ft. of grate per hour.
6. DON'T permit any pipes or boiler surfaces to remain uncovered, unless it is necessary to transmit the heat through the surface of that pipe to the room in which it is located.
7. DON'T permit any joint in the boiler or any pipe connected thereto to leak.
8. DON'T permit any valve to leak which is located on a pipe supplied by the boiler. This is a very common source of loss. All valves should be positively tight when closed.
9. DON'T attempt to control the quantity of condensation to be collected from any pipe or other apparatus by hand control. There are a large quantity of good serviceable traps to collect these returns of condensation and they should be returned from these traps to the boiler.
10. DON'T permit any surface on the boiler exposed to the furnace heat to become covered with soot or ashes. The tubes should be cleaned at the very least daily.
11. DON'T use live steam for heating rooms, liquids, or other substance when there is exhaust steam from engines or pumps available. If the exhaust steam is not of sufficient temperature to heat the room, the liquids, or other substance to the required temperature, arrange your heating to be done in two stages; for instance, water could be heated to nearly 212 degrees by exhaust steam, then passed through to another vessel to be heated to the desired temperature with live steam.
12. DON'T feed a boiler with cold water when there is exhaust steam available to heat it. Every eleven degrees in temperature that feed water is raised by heating by exhaust steam there is a saving of 1 per cent. in fuel, and in winter time especially feed water is very seldom any warmer than 42 degrees. If this water is heated 212 degrees it will then effect a saving of 15 to 18 per cent.
13. DON'T allow the main steam valves on any engine or pump to leak. This is a very common fault, due to the fact that the leak is not seen.
14. DON'T allow the piston of any engine or pump to leak. This is also a very common defect permitted to go on day after day simply because the leak is not seen.
15. DON'T take it for granted that pipes that lead to sewers, blow-off tanks, or other places of discharge, are tight. If the pipe is warm between the stop valve and the source of discharge it will generally pay to investigate a little closer, because it generally is a sure sign of waste with great profit.

Distributed with the Compliments of the
CANADIAN MANUFACTURERS' ASSOCIATION

Association and Personal

PERSONAL

Robert Law Benson, assistant city engineer of St. Boniface, Man., died at his home on Jan. 2, at the age of 53 years. Mr. Benson was a native of Hamilton, Ont., and had been in the Winnipeg vicinity nine years.

John M. Park, member of the boiler-making firm of Park Brothers, and one of Chatham's most prominent business men, died at his home on Queen Street, Chatham, Ont., on December 24. He was 57 years of age.

W. H. Milner, who was elected to the directorate of the Southern Canada Power Co. recently, at the annual meeting in Montreal, is president of the Miner Shoe Co., Maisonneuve, and vice-president of the Miner Rubber Co., Granby, Que.

William Earle, C. E., died last Saturday at the residence of his father-in-law, Senator Domville of Rothesay, near St. John, N.B. He had done engineering work with the C.P.R., was former manager of the St. John Street Railway, and latterly was District Engineer of Dominion Public Works in Manitoba.

Frederick Triebel died at Montreal on Jan. 1. Mr. Triebel, who was born at Cohoes, N.Y., 67 years ago, came to Montreal and entered the service of the Ogilvie Flour Mills, where he was head mill wright for twelve years. He was also for thirteen years mechanical engineer for the Canadian Rubber Co.

William Clark Hawkins, managing director of the Dominion Power and Transmission Co., of Hamilton, Ont., has been elected president of the Southern Canada Power Co., of which he was already a director. Mr. Hawkins was born at Orange, N.J., in 1866. He became associated with the D. P. & T. Co. in 1901, and was appointed managing director in 1912.

Lieut. George H. Forster, who, before going overseas was manager of the Linde Canadian Refrigeration Co., Montreal, has been badly gased in the recent fighting while serving with the British army. Although his condition is serious, there is hope of his recovery. Lieut. Forster joined the 148th McGill Battalion, under the command of Lieut.-Col. Magee, and left in 1916 for England, but later was transferred to the Imperial Forces.

C.A.S.E. Exhibitors' Association.—The 29th Annual Convention of the Canadian Association of Stationary Engineers will be held at London, Ont., June 25, 26 and 27. As unanimously decided at the last annual meeting, the usual exhibition of power plant supplies will be held. The feeling of the meeting was that the convention and exhibition teach economical and efficient methods in the power plant and thus assist in the national effort to induce industrial production. London is a good centre for the convention, being a large growing city in the centre of Western Ontario, with distributing lines leading to all the important towns and cities in the western part of the province. Full particulars regarding hall and other arrangements will be available at a later date. The secretary is Gordon C. Keith, 32 Colborne Street, Toronto.

HAMILTON BRANCH C.A.S.E. DISCUSSES FUEL AND FLUE GASES

A PRACTICAL and instructive paper, illustrated with diagrams on a black-board, entitled "Fuel and Flue Gases," was read by J. S. Cooke, Belleville, recently in the Orange Hall, North James street, to members of the local branch of the Canadian Association of Stationary Engineers. The meeting was presided over by John Hale, local president. The affair being open, many local engineers interested in the subject were in attendance. Mr. Cooke touched on troubles met with in the operation of boilers which the modern stationary engineer has to combat. The speaker emphasized the fact that through faulty construction of furnace chambers considerable fuel loss was caused by incomplete generation of available heat units, these escaping without serving their full purpose.

Mr. Cooke also touched on black smoke, which, he said, could be seen emanating from innumerable chimneys throughout Canada. If Canada's manufacturers and those in charge of government and municipal and other institutions would only seriously grapple with this very important question many thousands of tons of coal would be saved annually. The speaker also said that the elimination of the black smoke nuisance would be a boon to residents who were often heard to complain about dirty houses and soiled curtains, caused by the escape of the filthy black smoke.

"You can always be sure that when clouds of black smoke are being emitted from a chimney the combustion is not in the right spot," said Mr. Cooke, "and those in charge of such boilers should take steps to counteract the escape."

Mr. Cooke urged manufacturers to take more interest regarding the installation of their boilers and furnaces. Far too much was left to the stationary engineer. The lecturer was accorded a vote of thanks at the close of his paper.

For Tuesday, January 15, President Hale announced a social time and dance, also a musical evening. Supper will be provided. An invitation is extended to the wives and lady friends of members, also unaffiliated stationary engineers. The affair will be held in the Orange hall, North James street.

OPERATOR ORGANIZATIONS

British Columbia Association of Stationary Engineers, Vancouver.—Subordinate Lodges at Vancouver, Victoria, New Westminster, Cumberland, Merritt, and Fernie.

North-West Association of Stationary Engineers, Edmonton, Alta.

Manitoba Association of Stationary Engineers, Winnipeg.

Power Canal Making Progress.—Excellent progress is now being made on the Chippawa Hydro-Electric Power Canal and the preliminary work has got well under way. The construction railway, which will carry away the material excavated, has been completed from the Whirlpool to the power house, and the rest of the line is being pushed forward. The Hydro engineers were handicapped by shortage of labor, but now about 350 men are employed. At the present time operations are being centred on the erection of a concrete bridge for the Niagara, St. Catharines and Toronto Railway tracks at Stamford, Ont. This is only one of about thirty bridges which will have to be built. The engineers are filling in a great many ravines around the Niagara River with the earth taken out in excavating the canal.

CONSERVATION OF FUEL

PROMINENT among the many problems with which manufacturers have to contend at the present time, under the stress of economic production, is that of the conservation of fuel owing to the failing of the immediate supply available for industrial and domestic purposes. Existing conditions make it almost imperative that every possible means be adopted to avoid unnecessary consumption or waste of fuel. Measures may be taken, however, to minimize the use of coal to the detriment of other vital and equally important factors of shop or factory operation. Under present circumstances, with a very evident scarcity of fuel, manufacturers may be tempted to forego the heating of their plants during the idle period over the week-end and a corresponding reduction each night. It may seem ridiculous to maintain a fairly warm temperature in a shop from which the workmen are absent for a period of from 24 to 36 hours. While the fuel saving from such a practice would undoubtedly be of considerable importance, it might be well to give more than passing attention to the possible consequences incidental to the unavoidable fluctuation of working temperature.

In many factories or workshops the heating is accomplished by the circulation of the exhaust steam from the engine; in others, the system may be supplied from the live steam from the boilers, or by means of forced hot water or hot air circulation. In any case it is often found that the closing hour is not only a signal to the workmen to knock off, but may also indicate the closing—in whole or in part—of the valves that control the passage of the heating medium from the source to the different "unoccupied" portions of the plant. It is, however, considered advisable, particularly in very cold weather, to always permit sufficient steam or hot water to pass through the pipes to prevent the possibility of freezing. This invariably eliminates piping troubles but creates other contingencies having vital bearing, although seemingly unimportant relation, on the output of the shop.

Early on Monday morning—sometimes after the men have started work—steam is forced through the heating system to warm up the shop, and after a period ranging from ten minutes to perhaps a couple of hours the atmosphere is quite comfortable; but what of the equipment? Metal machinery, especially of a bulky character scattered about a spacious shop, will seldom attain a very high temperature, even in summer weather, unless subjected to the heat of an adjoining furnace or other radiating unit. When the workmen leave a factory and the heat is partly or entirely shut off the proportionately large volume of metal rapidly absorbs the heat from the atmosphere, and then continues to fall until the return of the men in the morning, when the machines are like so many blocks of ice. This order of things is not conducive to an early start, as the men seldom show any great desire to freely handle the cold equipment.

Apart from the evident inconvenience to the operators, the fact that unavoidable delay may be necessary in getting a machine into action, a cold shop is a thing to be avoided. Where accuracy is a feature of the work, and rigid inspection is adopted, it is essential that extreme variations in shop temperature be avoided as far as possible. Under these conditions normal temperature is a very important and necessary factor. Even confining the question to the actual saving of fuel, the result may be open to discussion, owing to the additional initial firing that is necessary to disseminate sufficient heat to meet the shop requirements.

The Operators' Point of View

DOES A PISTON STOP AT REVERSAL?

By N. G. Near

THE writer has read R. Hamilton's arguments in December POWER HOUSE under the above heading with much interest and notes the very clever way in which he endeavors to prove that a piston does not stop at reversal.

A line has no thickness, true enough. It therefore requires no time at all for a crank pin to pass through a line. Therefore, Mr. Hamilton argues the cross head does not stop. That being the case, then, it can be proved that a piston has no "maximum velocity" either. Draw your cross head velocity curve and it will be found that at one "point" the ordinate is longest. The height of that ordinate represents the maximum velocity as taught in most of our text books and the writer has always accepted it as being true and must continue to do so. According to Mr. Hamilton's way of looking at it, though, this solitary maximum being represented by a "point" and a point having no magnitude it takes no time at all for the crank pin to pass through that point and therefore the maximum velocity does not exist (theoretically).

I am attempting, you see, to answer Mr. Hamilton's arguments with his own "thunder" and could probably go all the way around the whole path of the crank pin and prove that our understanding of kinematics is all wrong because of the smallness of a point.

To the question, "How long does a piston stop?" there can probably be only one answer—zero seconds. It doesn't stop a hundredth of a second, a thousandth, a millionth, a billionth, or even a decillionth for such stops are all of longer duration than zero. A stop, as is generally understood, means zero velocity and we surely have a "point" in our velocity diagram where the velocity is zero in the same way that we have a "point" where the velocity may be 10 feet per second regardless of whether the cross head is accelerating or decelerating.

Mathematically, let us assume a case where the length of the connecting rod is infinite and the velocity of the crank pin is C feet per second. The velocity of the piston may then be given as v=C sinA where A is the angle between the crank arm and the line through the shaft and piston. Now, where A is equal to zero the v becomes zero and for that infinitesimally short time the piston STOPS because its velocity is zero. Where the connecting rod is of finite length a similar solution will give the velocity at this "point" as being zero.

True, this may seem like some "pretty fine figuring" and Mr. Hamilton has a strong line of arguments built up on the fact that "zero is nothing" and that if a piston stops zero seconds it doesn't stop at all, which sounds logical because of the play on the words. But everything points to a dead stop via the velocity diagrams and mathematical formulae.

Anything possessing weight must stop before it can be made to reverse in its tracks" as the expression goes. Even a baseball comes to a dead stop when struck by a bat before it can move in an exactly opposite direction. The bat when swinging toward the ball, moves at a fairly constant velocity and is little disturbed when it meets the ball because of its greater mass. The whole bat does not stop because its direction is not reversed although some of the fibres in the bat may stop. But the ball DOES stop. The elasticity of the ball permits it to withstand the shock.

Perhaps all "points" in the ball do not stop at once but nevertheless every atom has its own deceleration and acceleration to perform and if the atoms do not function thusly our philosophy is all wrong.

DOES A PISTON STOP AT REVERSAL?

A PISTON does stop at reversal and I believe it is possible to slow an engine down so slow that every one will admit that it does. Of course, external power would need to be used to run it at such a speed. Now if it actually stops while the fly wheel is turning very slowly, it must also do so at faster speeds. The fly wheel and shaft upon which it revolves have different motions. The outside edge of the wheel travels the faster, but in a constantly changing direction. The speed decreases from the edge to the centre of the shaft where there is no speed but a constantly changing of position, so no matter how slow the wheel moves no part of it or the shaft to which it is firmly fixed can be said to have stopped.

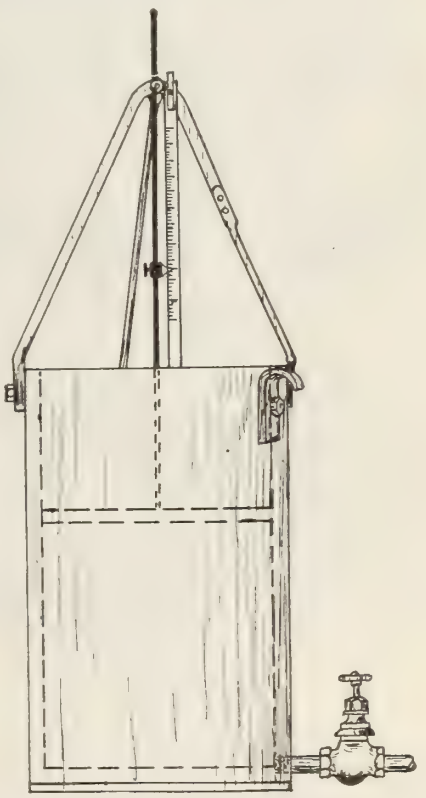
Move a wagonwheel over a knife-edge, and although there is no motion where the wheel is in contact with the knife-edge, there is a constant changing of position the same as in the centre of the shaft, so that no part of the wagon wheel can be said to have stopped.

If a solid body does not change its shape, it is impossible to move one part without moving the whole. One end of a spring can be held at rest while the other part moves. So also with an auto tire, when a given point on the face of the tire comes in contact with the ground the spring of the tire allows that point to stop while other parts are in motion. Some part of an auto tire therefore is at rest all the time while no part of a steel wagon tire rests as long as the wagon moves.

FUEL MEASURING TANK

By D. O. Barrett.

IN taking fuel consumption tests of internal combustion engines, the writer has found the tank shown in the cut to be the most satisfactory method of measuring the amount of fuel used. The tank is a cast iron cylinder accurately bored and the measurement taken. A float is provided in the tank, three arms being attached to the float, so that it will remain central and prevent the rod attached to the float being bent when the tank is moved. To this rod is attached an indicator moving along a 24-in. steel scale graduated in hundredths, this scale being supported by the brackets shown. The tank being rather heavy, hooks were provided so that it could be easily lifted by the crane. The size of the tank to be used, of course, depends upon the size of engines to be tested, but should be large



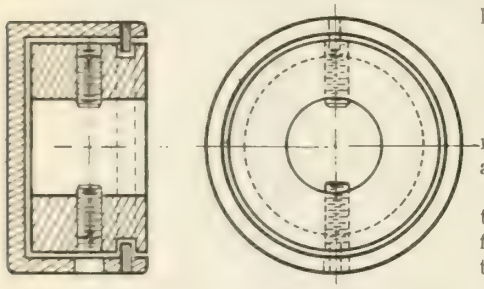
FUEL MEASURING TANK.

enough so that any ordinary run may be made without the necessity of refilling. The one shown was bored to 15.995 in., so that each inch in height represented 0.867 U. S. gallons. Readings being made on the scale graduated to hundredths could thus be made very accurately and easily. These readings could be transferred to pounds after determining the gravity of the oil. This method is much more accurate and quicker than when the fuel is weighed, as the average scales are not accurate and then a balance must be taken each time.

SAFETY-COLLAR FOR EXPOSED SHAFT ENDS

By J. Wright.

A VERY suitable protective means for preventing workmen from getting caught on the exposed ends of overhead shafting is the end safety-collar, shown in sketch. It consists of an inner collar having two headless screws for fastening this to the shaft. A loose fitting outer collar is placed over this. The inner collar has a square groove near the edge, cut reasonably deep, and wide enough so that the two pins fastened in the outer collar will hold it in position, while allowing the



SAFETY COLLAR FOR EXPOSED SHAFT ENDS

shaft and inner collar to revolve freely.

The shaft hole in the inner collar can be made large enough so it can be used on shafts of different diameters, it being only necessary to adjust the screws, and for this purpose a hole is made in the outer collar to insert a screw-driver.

It is readily seen that pressure on the outer collar from a workman's arm or sleeve will cause it to stop instantly, preventing damage such as would be done by the bare end of a revolving shaft.

HELPFUL HINTS

By John Kingston.

LOOKING through my scrap book of items cut from technical papers, I note several items which might be of help to readers. I believe these are not printed in books so far as my own knowledge ...

If brass work requires polishing or tarnishes quickly mix one quart of pure benzoin and eight tablespoonfuls of tripoli powder, shake well while using. A cheaper polish is ¼ ounce of oxalic acid dissolved in one pint of soft water.

To prevent polished steel tools from rusting, warm the tools and dip them into a solution of washing soda.

Two ounces of flower of emery and one ounce of soft soap mixed together into a paste make an excellent article to polish steel. A small quantity of this same paste spread over a piece of smooth wood makes an excellent sharpener for knives, giving them a very sharp edge.

If you wish to lag up a pulley with leather, a tablespoonful of glycerine and one gill of the best glue mixed with a little warm water will cause the leather to adhere nicely to an iron pulley.

For dirty boiler fronts, a good covering which will stand heat without blistering is a mixture of quick drying varnish and powdered soapstone.

A paint often used is a mixture of silica, graphite, and boiled linseed oil mixed to the consistency of ordinary paint; this makes an excellent boiler front covering.

A short rule for calculating the horse-power that a given shaft at a given speed will transmit is as follows:

$0.013 \times D^3 \times N =$ horse-power. This is for light shafts, which carry, say, only pulleys.

For shafts carrying gears use: $0.01 \times D^3 \times N =$ horse-power.

For shafts which are heavy, such as main line shafting, use: $0.008 \times D^3 \times N =$ horse-power.

In the foregoing,

D = diameter of shaft.

N = number of revolutions per minute.

The statement is made that these short rules can be relied upon as being fairly accurate.

Some simple rules for ascertaining the transmitting power of belting, without first computing the speed per minute that it travels, are as follow:

D = diameter of pulley in inches.

R = number of revolutions per minute.

W = width of belt in inches.

For double belting:

$$\frac{D\ R\ W}{2{,}100} = \text{horse-power.}$$

For single belting:

$$\frac{D\ R\ W}{330} = \text{horse-power.}$$

Another rule which can be used approximately for single belts is as follows:

S = speed of belt in feet per minute.

W = width of belt in inches.

$$\frac{W\ S}{900} = \text{horse-power;} \quad W = \frac{900 \times \text{h.p.}}{S}$$

$$S = \frac{900 \times \text{horse-power.}}{W}$$

For double belts:

$$\frac{W\ S}{630} = \text{horse-power;} \quad W = \frac{630 \times \text{h.p.}}{S}$$

$$S = \frac{630 \times \text{horse-power.}}{W}$$

The statement is made that these formulas are based on an average breaking strength through the lace holes for single leather belts of 200 lbs. per inch of width. Taking 3 as factor of safety for belts:

$\frac{200}{3} = 66\ 2/3$ pounds safe working stress per inch width.

Effective pull on belts $= \frac{\text{horse-power} \times 33{,}000}{\text{Velocity in ft. per minute.}} = \text{E.}$

The example given is as follows:

A 36 in. driving pulley at 150 rev. per min. required the width of belt to transmit 6 horse-power. W = width.

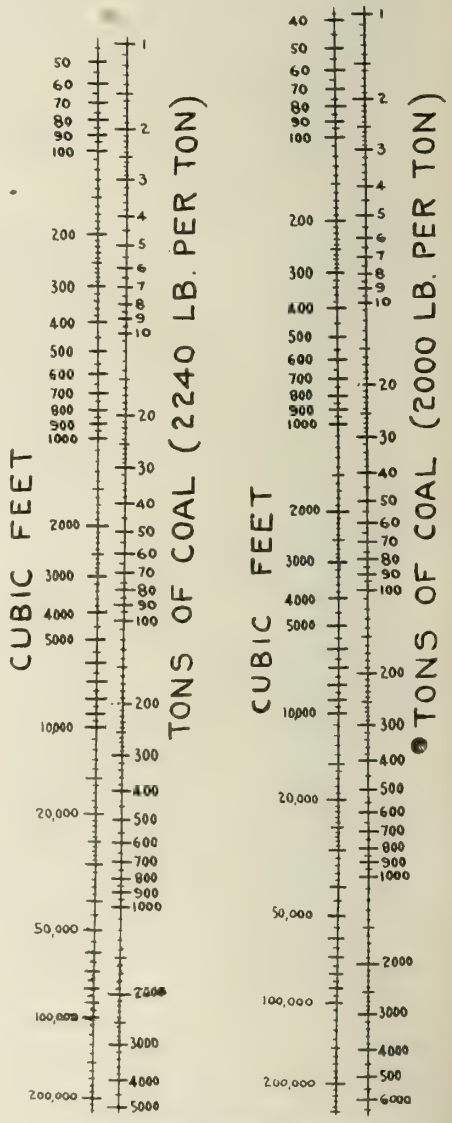
$\frac{36 \times 3.1416 \times 150}{12} = 1413.72$ ft. per minute.

$\frac{6 \times 33{,}000}{1413.72} = 140$ lbs. $= \frac{140}{66.67} = 3$ in. wide.

HANDY COAL CONVERSION SCALES

By N. G. Near.

THESE scales will be found useful for determining the number of tons of coal



COAL CONVERSION SCALES.

in any given number of cubic feet up to 200,000. One scale is constructed on the basis of 2,000 pounds per ton and the other on the basis of 2,240 pounds per ton. The scales are so simple that ex-

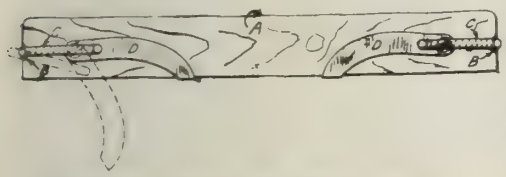
planation is hardly necessary. One thousand cubic feet, for example, would contain either 24 tons or 27 tons. Just glance across from scale to scale and either may be instantly converted into the other. Thus, if it is desired to find how large a bin must be made to hold a given number of tons, these scales will tell in a second the exact number of cubic feet volume necessary.

The scales are usable for either anthracite or bituminous coal. There is very little difference in the weights of these two coals. Many coal men seem to think that anthracite is considerably heavier, but that is not so. Anthracite is a trifle heavier, but not enough to affect results much. The scales may, therefore, run a little low for anthracite and high for bituminous coals, but for all practical purposes they will do very well, for, as is well known, no two coals, even from the same mine, are exactly alike in every particular.

CLAMPING BLOCK FOR EMERY CLOTH

By R. Hamilton

WHEN it is required to fasten emery cloth or sand paper to a block of wood the general practice is to fasten the cloth on the wooden strip by means of small tacks; the sketch here shown illustrates a very handy and serviceable device for this purpose and one that can be easily made from a small piece of



CLAMPING BLOCK FOR EMERY CLOTH.

wire and sheet steel stock. The wooden block can be made of any desirable size and by cutting a groove in each end as shown at B will provide an efficient means for clamping the cloth by means of the toggle arrangement of the U-shaped wire and clamping lever D. The dotted line shows the clamp open to allow of inserting the cloth which is placed over the top A and between the end of the block and the wire C. When the cloth is in position the piece D is pressed back against the block so that the center line of the wire C is forced over the center of D, thus locking the toggle and also the cloth in position.

A WATER LEVEL ALARM

By J. O. McDonnell.

THE illustration shows an electric low water alarm which rings and sets automatically. It is arranged on a tank used for holding condensation from a large hot water heater and other steam-heated articles, and is then used for feed to steam boilers. Very often tanks used for this purpose are placed in an adjoining room or some other remote place where it is difficult for the man in charge to know when the tank is empty, allowing the pump to over-speed and likely become damaged.

Take a piece of board about four inches wide and long enough to reach across the tank. A square hole is cut about the centre for the rod of the float A to pass through as shown at B, Fig. 1. The rod is a piece of light wood made square to fit loose in the hole, so it will work up and down easily with the raising and lowering of the water in the tank. A support is fastened under the board, extending down about 4 in., which

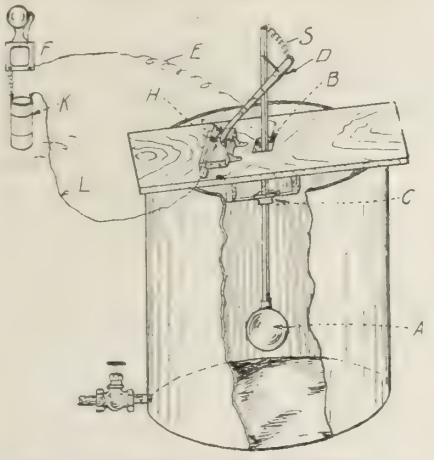


FIG. 1. GENERAL ARRANGEMENT OF WATER LEVEL ALARM.

the rod also passes through to prevent it from swaying, as shown at C. A piece of heavy sheet copper, 8 in. long, ¾ in. wide, cut to the shape shown at D, is fixed to the float rod to swing loose with a small bolt or screw nail, and to it is attached the wire E from the fell F. A small wooden block, 3 in. long, 1½ in. wide, ¾ in. thick, is fixed to the board with a small hinge, as shown at H. A piece of sheet copper is fastened across the block close to edge, with one end extending about ½ in., to which the wire L from battery K is attached. The copper arm D is fixed to the float rod with a small screw nail, so the hook end will come about the centre of the block and will slide out as the float lowers until it passes over the copper plate, which is about ⅛ in. wide, and drops over the side of the block (see A, Fig. 2). The bell tached to keep the arm D pressing

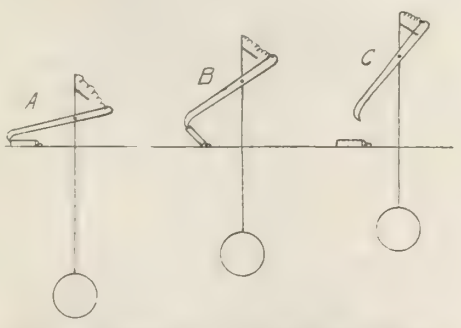

FIG. 2. DIAGRAM ILLUSTRATING OPERATION OF WATER LEVEL ALARM.

rises the hook will turn the block back on its hinges, as shown at B, Fig. 2, when it will slip off and allow the block to drop back on the board. This arrangement prevents the arm making contact with the plate when the float rises.

The bell or battery may be fastened to any window or door frame where it can be distinctly heard. This article is very easily made, and will be found very useful in other places working under similar conditions.

Take a piece of board about four in

RESISTANCE OF AN OIL TO EMULSIFICATION

WHEN oil is used over and over again, as is the usual practice in large power plants, it may emulsify in a few days, if it is not of good quality, and have to be thrown away, as it will not pass through the filters. In order to arrive at a definite knowledge of the emulsifiability of oils, the United States Bureau of Standards has carried out investigations, the results being embodied in Technologic Paper No. 86, entitled "Resistance of an Oil to Emulsification."

To avoid the waste of time and the inconvenience of actually trying the oil in a turbine or other machine, a laboratory test has been devised by means of which it may be predicted whether or not the oil would give satisfaction in service.

The test consists of violently stirring a small sample of the oil with water under standard conditions. Then the oil that will separate out from the water the most rapidly is the best oil for turbine lubrication, other things being equal. It is found that most of the oils on the market are either very bad or very good, and that there is no difficulty in finding turbine oils that will settle out from the water in a minute or less after stirring as described.

For some other purposes it is desirable that oils should emulsify readily; and the test shows that oils of this class, when subjected to the same treatment as the turbine oils, will not separate at all in one hour, nor completely separate in one year. When turbine oils are used for months or years without renewal, they gradually deteriorate until they emulsify readily, even though they are very good oils to start with. The conditions of use in different plants are so different that it would be impossible to predict just how long a given oil would last, but it is believed that any power-house engineer, by the use of this test, could keep track of the deterioration of his oil and thus discover when it is time to clean out his lubricating system.

Niagara Power Released for Buffalo. —Between 80,000 and 100,000 electrical horse-power has been released in Niagara Falls under an order received by the Hydraulic Power Co. and the Niagara Falls Power Co. from the United States Government. Electro-chemical companies working on important war orders will receive power diverted from plants engaged in the manufacture of non-essentials. There will be a general scaling down of the power received by the latter and in some instances large concerns will be cut off entirely. The two power companies are now producing a total of 278,000 horse-power, about 40,000 of which has been coming to Buffalo.

Operators' Instruction Course

EDUCATION PAPER—IV.

AT what rate must water be evaporated per horse-power?

The boiler horse-power corresponds to the evaporation into steam of 34.5 lbs. of water per hour from a temperature of 212 deg. and at atmospheric pressure, or, as it is commonly expressed, from and at 212°.

* * *

What does a dynamo consist of?

The dynamo is a machine for converting mechanical energy into electrical energy. It consists of two elements—a stationary field, which produces the flux or lines of magnetic force, and the revolving element, the armature, which carries the coils of wire, in which are generated electromotive forces, due to the cutting of the lines of force of the field. The simplest form of dynamos must have two poles—a north pole and a south pole, and any increased number of poles would be a multiple of two. Thus a dynamo may be of 2-pole or bipolar, 4-pole, 6-pole and so on. The poles are simply bobbins of wire wound in iron cores and these cores are attached to the inner circumference of a ring of magnetic iron called the yoke.

An armature is a cylinder of iron, usually built up of thin laminations to keep down eddy currents, assembled on a shaft and bolted tightly together. The outer surface of the armature is slotted to receive the sides of the coils which form the winding. These coils have their sides embedded in the slots and are so arranged, grouped, and connected that their electromotive forces will add up and give the total voltage of the machine.

The armature is mounted between the field magnets and the ends of its shaft are supported either by pillar bearings from the base if the machine is a large one, or by the end housings which are bolted to the magnet ring or yoke and provide the bearings for the shaft.

The ends of the field poles next the armature are called the pole faces, and these faces are shaped to the curvature of the armature and are so dimensioned as to best distribute the flux through the windings on the armature.

Between the stationary pole faces and the revolving armature there must be left a clearance, and this is called the air gap. It is desirable to keep this gap as small as possible, because the flux has to cross this gap before it can thread through the armature coils, and as air is a poor conductor of flux compared to iron, some of the flux shows a reluctance to crossing the gap twice, as it would have to do to complete the magnetic circuit between the north and south poles. Rather than take the path of high reluctance through the armature it will jump across from one pole tip to the other pole tip, and consequently becomes lost as effective flux for producing electric current. Hence to avoid this flux leakage the air gap must be kept as low as possible.

If the dynamo is to deliver direct current it will have a commutator mounted on the armature shaft, to which the ends of the armature coils are connected.

Two sets of brushes are provided—the positive and negative. The brushes make contact with the commutator at the neutral point so as to short circuit and reverse the current in the coils at the moment when they would be tending to generate an e.m.f. in the reversed direction. The brushes collect the rectified current from the commutator.

If the dynamo is of the alternating current type it will not need to rectify the current, and hence no commutator will be used. Instead the single phase or polyphase alternating current will be collected through brushes bearing on slip rings.

* * *

What does an electric motor consist of?

The electric motor is a machine for converting electrical energy into mechanical energy. Generally it is the same as a dynamo, only its operating conditions are reversed. It consists of magnetic field poles attached to the yoke with the armature.

* * *

How is an electric current generated?

Electric current is generated whenever a coil of wire, which forms a completed circuit, is rotated in an electric field, so that the number of lines of force which it encloses is constantly changing. The principle on which the generation of electricity depends is that of electro magnetic induction, by which an electromotive force is induced in a coil of wire in which the number of enclosed lines of force is varying. This induced e.m.f. causes a current to flow around the circuit and is proportional to the number of lines of force cut per second.

* * *

What is a commutator?

The commutator of a dynamo or motor consists of a group of copper bars or segments arranged side by side, so as to form the outside of a cylinder. Sheets of mica insulate each bar from its neighbor and from the iron shell and clamping rings that hold the bars in place. The commutator is mounted on the shaft near the armature and rotates with it, and the armature conductors are so connected to the commutator bars that the alternating current generated in the windings is changed to direct or uniflow current at the terminals of the machine by means of the brushes which make contact with the commutator surface. These brushes make contact with the bars to which the coils undergoing commutation or reversal in direction of current are attached, and must be so placed that the contact between proper bars and brushes is effected at the instant when the coil, undergoing commutation, is cutting no lines of flux. This point or setting of the brushes is called the neutral point, and is the proper place for the brushes to secure sparkless commutation.

* * *

What is a refrigeration ton and its relation to ice-making capacity?

The heat required to melt one ton of ice (2,000 pounds) at 32° F. would be $2{,}000 \times 142.2 = 284{,}400$ B.t.u., and so the refrigeration ton corresponds to the absorption of 284,400 heat units. For a refrigeration machine this same amount of refrigeration would be produced by expanding 510 pounds of ammonia from a liquid to a vapor.

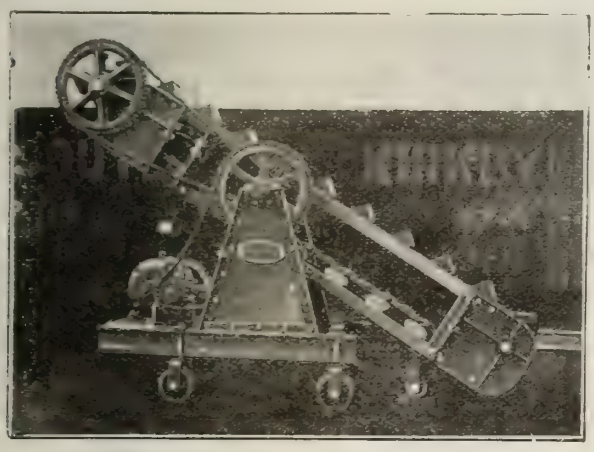
On what principle does the ammonia absorption system work?

The operation of an absorption refrigeration system is as follows: Aqua ammonia, obtained in metal drums from the ammonia manufacturers, is admitted to the generator, and steam, either live or exhaust, according to the type of the machine installed, is admitted to the steam coils of the generator. This causes the liquid to boil and the contained ammonia gas to rise, taking with it from 8 to 10 per cent. of water vapor. This water vapor is removed by condensation in the rectifier, and the ammonia vapor then flows into the condenser, where it is condensed to a liquid state by the action of the cooling water flowing over or through the condenser. From the condenser the liquefied ammonia flows to the liquid receiver, then through an expansion valve into the evaporator, where the liquid expands into a gas and absorbs heat. The gas is then drawn back to the absorber to be absorbed and enrich the weak liquor from the bottom of the generator. The rich liquor is then pumped back to the generator to go through the same process over again.

Progress in New Equipment

A PORTABLE ELEVATOR

MANY industrial processes involving the handling or transport of materials could be performed with greater speed and efficiency and with a large saving in labor,. but in many of these cases the installation of a fixed or elaborate conveying system would not be practicable or justifiable, owing to the changing venue of operation or the irregular, possibly infrequent, and not always calculable periods when its use would be required. Such conditions are admirably met by the use of portable elevators or conveyors. They can be brought into use as and when required; they can be moved from place to place with the greatest ease, and they can be arranged so that the work of loading and unloading can be carried out by merely reversing the running.



PORTABLE COAL ELEVATOR.

The accompanying engraving shows a small portable coal elevator of this type which is manufactured by the firm of E. Bennis & Co., Bolton, Lancs. It is 10 ft. long between centres of the drums and has buckets 8 in. wide.

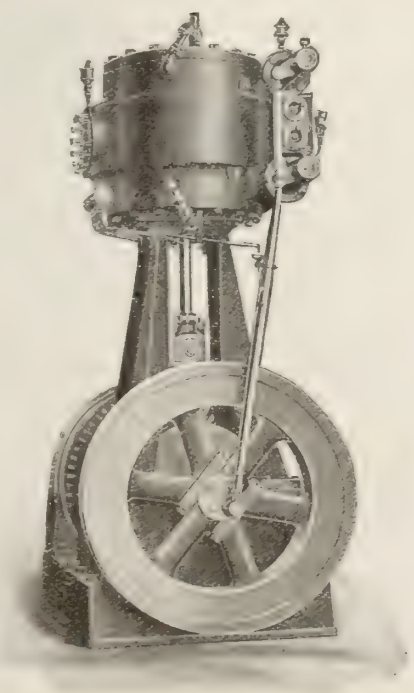
The elevator is mounted on a portable truck in such a manner that the angle of the elevator can be altered if desired. The truck is built out of mild steel sections and is carried on four rollers.. All the rollers are attached to pivoted axles. The top of the axle is made with a square so that it can be turned round with a spanner, and provision is made for locking the wheels in four positions. The elevator is driven by two chain drives. Two sprocket wheels are placed on the pivot shaft. One of these sprockets is driven direct from the motor, and the other sprocket drives the elevator shaft, so that the relative centres of the shafts are maintained irrespective of the angle of the elevator. When in operation, the elevator is pushed up to the coal heap, and the coal trimmed forward to the buckets.

MOTOR DRIVEN DRY VACUUM PUMP

THE makers of the dry vacuum pump illustrated in the accompanying engraving are the Wheeler, Condenser and Engineering Co. of Carteret, N.J., who have endeavored, in its design and construction, to provide an air pump for use on condensers, which will satisfactorily fulfill the requirements of such an apparatus in both marine and stationary applications.

It is especially adapted for use in that type of installation where it is desirable to maintain a high vacuum in the condenser, in which case the use of separate condensate and air pumps is approved practice.

As the cut shows the pump is of the vertical type and is driven by an electric motor direct connected to the crank shaft. The inlet valves of the pump are of the semi-rotative type, which are so manipulated by the valve gear as to draw air from the condenser during its full stroke. Clearance difficulties are eliminated in this design of valve gear by providing ports which register with an equalizing air passage. The discharge valves are of the poppet type and are easily accessible, as are all the wearing parts, and their method of arrangement ensures adequate drainage of condensed vapor.

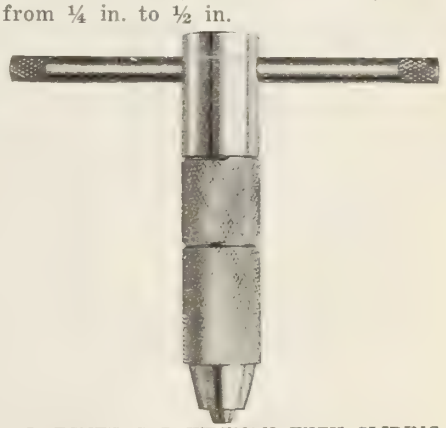


MOTOR-DRIVEN DRY VACUUM PUMP.

Advantages claimed for the electric driven rotative dry vacuum pump over the reciprocating steam drive are: ease of installation; less attention required; no steam pipe radiation losses; and improvement of plant load factor.

RATCHET TAP WRENCH

THE accompanying engraving illustrates a ratchet tap wrench which has recently been placed on the market by the Moss-Ochs Co., Cleveland, O. It is made in two sizes: No. 1, from 0 to ¼ in.; No. 2, from ¼ in. to ½ in.



RATCHET TAP WRENCH WITH SLIDING T-HANDLE.

The device is of strong and substantial construction and consists of a chuck mounted on a shank provided with a double acting ratchet. The T-handle fitted to the upper part of the shank is held centrally by means of a dog which automatically fits in a flat milled on the handle. When required for use in corners and other difficult or awkward situations, the handle slides to either end, which action, combined with the ratchet movement, removes considerable worry from the operator, avoids to a great extent the breakage of small taps, and enables more accurate work to be produced.

The ratchet is immediately adjustable for right or left action by simply turning the milled sleeve shown above the chuck.

The Lack of a Grease Extractor Cost Them $5.000.00

We can't give the actual name of the college power plant at which this neglect took place.

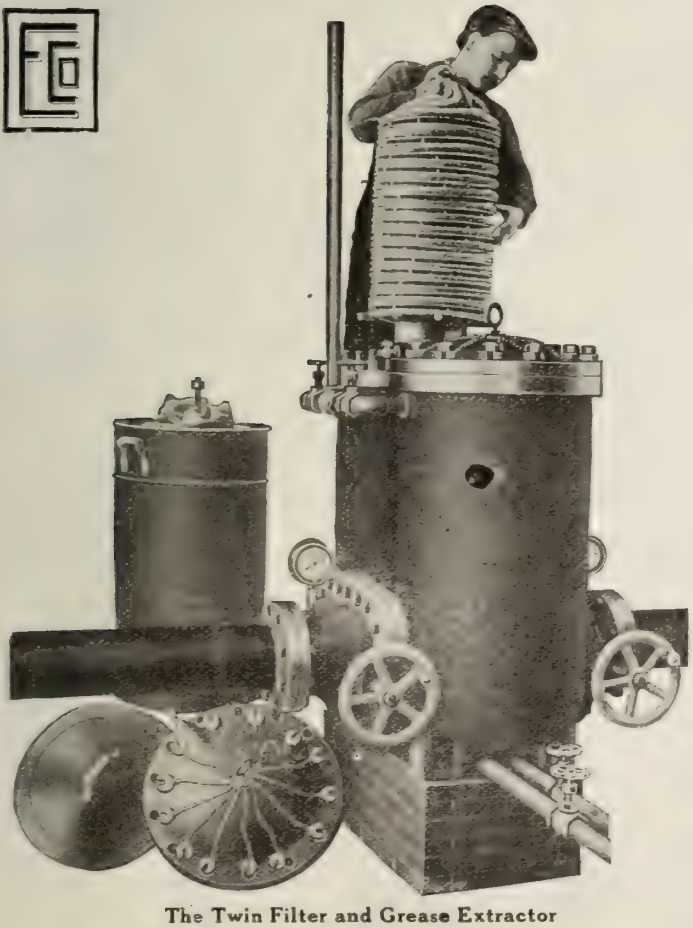
Naturally no plant wants to be connected with a true story like this.

But here are the facts:

Oil was allowed to get into the boilers and four of them were ruined by sagging—it cost $5,000—get that, five thousand in cold cash to reset these boilers.

With the reset boilers, a Twin Grease Extractor was installed and—

They have had no trouble since.



The Twin Filter and Grease Extractor

Avoid the Danger of This—Install a Twin Grease Extractor

This actual case proves again how much better it is to use the ounce of prevention. Keep oil out of your boilers thoroughly, efficiently, safely with a Twin Grease Extractor.

You'll find unusually good features in the "Twin." For instance, you can clean it easily—a very important point. But more important, the twin idea: two separate filtering chambers—while one is in service, the other can be cleaned without by-passing or interrupting the flow of water.

You'll find a complete description in our Bulletin B. Send for a copy.

Belleville, Ont.—The Town Council contemplate the installation of an electric pump.

Renfrew, Ont. — The Town Council contemplate the purchase of pumps for the waterworks.

Brussels, Ont.—The town is anticipating the installation of a new electric light plant shortly.

Alliston, Ont.—The Town Council propose electrifying the municipal pumping plant if the by-law passes.

Toronto, Ont.—The townships of Scarborough and Etobicoke propose to instal water distribution systems.

Valleyfield, Ont.—The power house at the Montreal Cottons, Ltd., plant was destroyed by fire on December 13.

Ingersoll, Ont.—An explosion of mysterious origin in the plant of the Ingersoll Gas Co., on Jan. 2, has almost

Sherbrooke, Que.—The City Council will build a dam at the civic power station and make permanent improvements at both power stations.

Lumsden, Sask.—The local electric light and power company will be purchased by the Town Council at a cost of $7,000.

Armagh, Que.—Plans have been drawn for the town council for waterworks costing $40,000. Engineers, Gouvin and Beauchemin, Quebec, Que

Toronto, Ont.—The contract for a new boiler house for the Swift Canadian Co., operate a faction in Toronto. Although Construction Co.

Galt, Ont.—A by-law will be submitted to the ratepayers on January 1 to provide money for extensions to the waterworks system to cost $18,558.

Toronto, Ont.—The Spruce Falls Pulp & Paper Co. have acquired pulp limits in the Kapukasing District, Northern Ontario, and will erect a pulp and paper mill.

Alliston, Ont.—A by-law will be voted on by the ratepayers on January 7 to authorize an expenditure of $6,000 for electrifying the municipal pumping plant.

Copper Cliff, Ont.—The Canadian Copper Co. have let the contracts for a new converter and building to the Allis-Chalmers Co. and the Dominion Bridge Co. respectively.

Burton Township, Ont.—The Township Council propose spending $55,000 on the purchase of necessary material and equipment for instaling an electric light system.

Kingston, Ont.—On Thursday afternoon Engineers Kribs and Johnson, of Toronto, turned on the Hydro-Electric power from the Trent at the Kingston sub-station, and everything worked satisfactorily.

Perth, Ont.—The municipality propose to raise $120,000 by municipal debentures and to purchase the local electric and waterworks plant from the present owners, the Canadian Electric and Water Power Co.

Whitby, Ont.—The following by-laws have been passed by the Town Council: $1,150 for construction of sewer laterals; $3,200 for low level pumping station; $5,700 for extension waterworks and electric light.

The Eugene F. Phillips Electrical Works, Montreal, has changed its name to that of Phillips, Ltd. The company has also been incorporated with a capital of $4,000,000 to engage in the manufacture of wire cables and electrical apparatus of all kinds.

H. Gray & Co. has been incorporated at Ottawa with a capital of $150,000 to manufacture mill supplies, cotton waste, greases, etc., The head office is at Montreal and the incorporators are E. E. Howard, J. DeWitt and E. A. Rose, all of Montreal.

The Wedgerite Piston Ring Co. has been incorporated at Ottawa with a capital of $49,000 to manufacture a patent piston packing, also engines and motors of all kinds at Montreal. The incorporators are Ulric and Ernest Duchesne and Charles A. Gareau, all of Montreal.

Mimico, Ont.—The council going in by acclamation left the only voting at Mimico in connection with a by-law to appoint a commission to take over the public utilities, the waterworks system and the Hydro. The by-law carried with a large majority. The members of the commission will not be voted on until next year.

Chatham, Ont.—Damage estimated at between $8,000 and $10,000 was caused to the plant of the Pittsburgh & Des Moines Steel Co. by fire which broke out on Sunday morning in the engine room at the plant. Heavy damage was done to the building and machinery. The roof at the west end of the building was demolished and the engine room was transformed into a mass of debris. The plant was formerly owned by the Chatham Bridge Co. and was recently taken over by the Pittsburgh & Des Moines Steel Co. as a Canadian branch.

Niagara Falls, Ont.—The Hydro-electric Power Commission of Ontario are going ahead with the construction of a new pipe line at Niagara Falls, running from the intake to the generating station, and paralleling those now in operation. It is expected this line will be completed by July, by which time also it is the intention to have extra turbine and generating equipment to the extent of some 25,000 h.p. ready for operation. Whether this will be in the form of two units similar to the latest additions to this power house, or whether one large unit will be installed, has not yet been determined.

London, Ont.—Sir Adam Beck announced here on Monday that he had awarded contracts for the construction of a 13½-foot wood stave flume with turbines and generators for the development of an additional block of 50,000 horse-power at the plant of the Ontario Power Co. at Niagara Falls. Of this additional horse-power 20,000 will be available in August next and the remainder in October. It is estimated that it will next winter save the importation of more than three-quarters of a million tons of soft coal, which at from $8 to

$10 a ton would represent an outlay of from $6,000,000 to $7,500,000.

Wallaceburg, Ont.—Damage to the extent of $100,000 was done on Dec. 11 by fire to the Wallaceburg plant of the Dominion Sugar Co. The fire followed an explosion believed caused by an explosion of gas used for reheating the dryers in the pulp building. The blaze completly destroyed the building and machinery and 7,000 bags of pulp.

Windsor, Ont.—The Water Commissioners have decided to instal at once two motor-driven pumps to obviate danger which threatened to arise as a result of the fuel shortage. It is proposed to use Hydro power to drive the pumps and to keep the present steam installation for auxiliary purposes. However, in order to relieve the load upon the Hydro system in the early evening the steam pumps will be used for an hour or two.

Chatham, Ont.—A serious situation has developed in Western Ontario on account of a shortage in supply of natural gas. The gas pressure failed in Chatham last Saturday, the available supply being hardly sufficient to keep water from freezing in the boilers. There is also very little coal in the city and a number of factories may have to close down. Unless there is a change in the temperature very little relief can be expected.

Hamilton, Ont.—At a special meeting of the Barton Township Council held last Saturday, it was proposed to enact a by-law for the purpose of raising $55,000 for the purpose of installing a Hydro system in the township. It will require $22,000 as a first investment to buy out the present system, the rest of the funds to be held for extensions, etc. The question will be placed before the electors of the township when they ballot for the municipal elections.

Niagara Falls, Ont.—A 13-foot woodstave pipe line will be laid from the river to Queen Victoria Park down to the development at the foot of the Falls. This pipe line will enable the Ontario Power plant to be developed to its full capacity, and will produce an extra 25,000 horsepower. The new pipe line will provide enough water for additional generators as well, and to utilize it tenders will be let for the installation of additional turbines, with penstock and generator complete. This will give another 20,000 horse-power available ten months from now.

North Vancouver.—The district of North Vancouver Council on November 29 passed a resolution authorizing the clerk to prepare a general loan by-law to provide the sum of $35,000 for waterworks purposes. The money, which in the event of this by-law passing at the general elections in January, is intended for the establishment of a waterworks system east of Seymour River. The principal need for such a system is to provide a steady and sure supply to the two large industries at Roche Point—the Canadian Robert Dollar Co. and the Vancouver Cedar Mills, Ltd.

CYLINDER LUBRICATION

A powerful microscope will disclose hundreds of irregularities on a bearing surface, no matter how smooth it may appear to the naked eye.

DIXON'S Ticonderoga Flake Graphite

will fill up these minute irregularities and form a smooth, durable veneer of graphite that is practically frictionless.

It will give better lubrication, cut the oil bills in half and eliminate wear and tear.

Send for Booklet No. 222-C telling more about this lubricant and method of successfully feeding dry graphite into cylinders

Chatham, Ont.—Electrification of a section of the Chatham-Wallaceburg division of the C., W. and L. E., with the use of Hydro power is being undertaken, and it is expected that cars will be moved by the power from Niagara for the first time shortly. Because of the shortage of fuel the company has found it impossible to generate sufficient power for the entire system, which reaches from Erie Beach to Wallaceburg.

Cheaper Power at Orillia.—The Water, Light and Power Commission has made a reduction of 20 per cent. in the rates, which will mean a total saving of over $12,000 per annum. This was rendered possible by the completion of the new plant at the Swift Rapids, which provides all the power the town requires for its industries, whereas formerly a large quantity had to be purchased from other sources in addition to what was obtained from the old plant at the Ragged Rapids. The power rate is now $13.50 per horse-power per annum for ten-hour power and $18 per horse-power for a 24-hour service. The light rates are correspondingly low, the consumers having their choice of flat or meter rates.

G.T.R.'s Annual Track Inspection Completed.—The annual inspection of track over the Grand Trunk Railway System has just been completed. This inspection has occupied six weeks, and has included a thorough examination of rails, ties, etc., on the 1,145 miles of main line, and on some thousands of miles of branch lines. The inspection party travelled over the system in a specially constructed car fitted with electrically-controlled devices for registering the efficiency marks gained by the various sections for excellency of track maintenance. There was the keenest competition between the various section gangs, foremen and supervisors for the honors which are given to the section considered to represent the highest standard of maintenance work. These inspection trips serve to increase the enthusiasm of the men engaged in this important branch of railroad work, and enable the officers to give the closest supervision to the maintenance of the track in a high state of efficiency.

Saving Slack Coal.—In the Canadian semi-anthracite mines and in practically all the sub-bituminous and lignite mines, the proportion of coal wasted as slack varies from 12 to 35 per cent. Everything possible should be done to encourage the use of this class of fuel and it would seem advisable to exact a royalty on total output and rebate all or a portion of the royalty on slack coal provided the same is utilized or marketed. Under the present leasehold system, royalty is exacted on merchantable output only, which, therefore, tends to encourage the waste of slack coal. Slack is produced during mining and handling of the coal and the amount produced is lessened by the use of mining machines and by care in handling.

Ottawa Hydro-Electric.—The Ottawa Hydro-Electric Commission has had another successful year. The increase in revenue for 1917 over 1916 shows the total revenue for the first year of the municipal plant $35,000 in 1916. The expenditure showed only $16,000 increase and of this amount $12,000 was for power.

The Liquid Air Society will in the course of a couple of months move their head office to Toronto. For the past several years the administration of the Canadian business has been done from the Montreal office; the factory at Montreal will still be maintained as a branch, and will continue to be the main production unit of the company's several branches.

Attention, Water Power Users
FOR SALE

Four standard 55-inch Crocker Turbine Water Wheels, fitted with graduating gates, complete with shafting, gears, etc. Wheels were manufactured by Jenckes Machine Company, and guaranteed to develop 150 H.P. when horizontal shaft is running at 150 R.P.M. when working under an effective head of four feet. Have never been used and are as good as new.

THE CANADIAN FAIRBANKS-MORSE COMPANY LIMITED

"Fairbanks Renewable Disc Valves

are strong in construction and service"

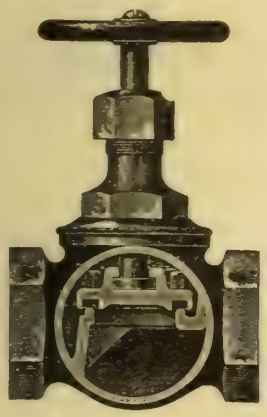
Every Engineer who has put them to a fair test will back up this statement.

In design they are very simple, containing few parts and all these interchangeable.

They are conservatively made; are heavier than the corresponding standard and heavy weights.

The Renewable Disc is the most effective ever produced. It consists of a recessed brass disc into which is spun a specially prepared Bakelite ring.

These discs can be replaced in less than a minute, without removing the valve from the line, and without the use of a single tool, except a wrench to unscrew the valve bonnet. Bakelite Discs have been proven by many experiments to have the longest life of any disc on the market.



Fairbanks will stand the hardest usage, and the most severe conditions of wet or dry steam.

The valve stems are packed with "Palmetto Twist."

GRATON & KNIGHT

Standardized Series

LEATHER BELTING

Tanned by us for belting use

There's a double tax on unstandardized belting

A belt unsuitable for the work to be done can lose money for you in two ways at once—

The first way is hard to detect. It occurs in the gradual slowing down of machines; in reducing output; in sapping production. It is simply "leaky power."

The second is a direct dollars and cents loss for expensive repairs and adjustments—an unnecessary loss if the correct belt had been installed originally.

The high cost of *unstandardized* belting was painfully discovered by a mill superintendent recently. It was necessary to replace a 24" 3-ply belt that had given long and profitable service. The superintendent shopped around—and decided to economize by getting a 2-ply belt of a different tannage. "I guess it will do all right," he said.

Here is the record of how that belt "did"—

Jan. 25	New belt installed (labor cost) - -	$26.99
Jan. 27	New belt taken up (labor cost) - -	9.06
Jan. 28	New belt found to be too light for the work. Taken off and returned to factory to have another ply added. Old 3-ply belt repaired and put back temporarily - - - - - - - - -	64.56
Feb. 15	New belt with extra ply added, cost of reinstalling - - - - - - - -	24.87
Feb. 22	New belt taken up - - - - - - -	22.87
Mar. 8	New belt taken up - - - - - - -	23.87
May 3	New belt taken up - - - - - - -	31.37
	Total expense	$203.59
May 7	Tests show efficiency of machine to be less than with the old 3-ply belt.	
May 15	Graton & Knight 24" 3-ply Heart Belt—the **standardized** leather belt for that job—installed.	

Are you being taxed by the wrong belting? If you are, the remedy is simple—standardize your belts. Let Graton & Knight representatives show you how

MACLEAN'S MAGAZINE for FEBRUARY

John Bayne Maclean — Robert W. Service
Agnes C. Laut — George Bernard Shaw
Archie P. McKishnie — Alan Sullivan, *et al.*

RAISING THE CANADIAN ARMY

The leading article in the February issue of MACLEAN'S MAGAZINE will give the inside story of the formation of the "First Thirty Thousand" and of the part **Sir Sam Hughes** played in it. It will bristle with stories never told before.

SOLVING OUR IMPERIAL PROBLEM

The second article by **George Bernard Shaw** will appear. It is headed, "The Folly of Ulster," but it lays down the basis on which the British Empire must be constituted after the war.

BEHIND THE CANADIAN LINES

A second article by a Canadian artist serving in France, **H. W. Cooper,** giving some unusual experiences and profusely illustrated with pen-and-ink drawings by the author.

FINDING THE MEN FOR WAR

An article dealing with the labor problem by **Agnes C. Laut.** It shows how acute the crisis in man power has become in Canada and the United States and suggests the remedy.

WHEN WILL THE GOVERNMENT START?

An editorial article on the need for immediate action on the part of the Government to increase food production in Canada during 1918—a strong indictment of government laxness

ROBERT W. SERVICE

Another stirring war poem in the new series by this master of martial verse, Canada's most famous poet.

SAFETY IN SUBSTITUTES

An article by **Ethel M. Chapman** on methods of food conservation during the winter months.

THE BALLAD OF THE FORTY SILENT MEN

A story of the battle of Cambrai in verse form by **Alfred Gordon,** a young Canadian poet of remarkable promise.

FICTION

THE WINNING OF YOLANDE

A delightful love story, the third and last of a series by **Ethel Watts Mumford.**

IN THE SHADOW OF OLD CREATION

A strong story of adventure by **Archie P. McKishnie.**

THE PAWNS COUNT

Another long instalment of the secret service serial by **E. Phillips Oppenheim.**

THE MAGIC MAKERS

Second instalment of the strong Canadian serial story by **Alan Sullivan.**

CAPTAIN CARLOTTA

A story of submarine chasing and of a mysterious invention by **W. Victor Cook.**

8 Pen records on clock driven chart.
9 Integrator driven from clock actuated disk.

That's all there is to it.

KEEPING BOOKS WITH THE BOILER

How many pounds of water are your boilers evaporating per pound of coal?

Are they doing 6 or 7 pounds, or just a shade better, or are they up to the top notch, say 10 or 11 pounds of water evaporated per pound of combustible?

The Cochrane Metering Heater tells how much you are getting for your money

Send for Catalogue No. 820.

Other Cochrane aids to boiler room economy include open feed water heaters, steam stack and cut-out valve heaters and receivers, metering heaters and independent meters. Sorge-Cochrane hot process water softeners, steam and oil separators, and multiport back pressure, atmospheric relief, flow and check valves.

Head Office: Toronto. Sales Offices: Montreal, Halifax, Sydney, Ottawa, Cobalt, South Porcupine, London, Winnipeg, Calgary, Edmonton, Nelson and Vancouver.

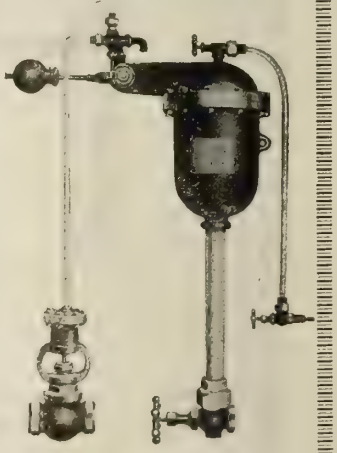
The Vigilant Feed Water Regulator



Perfects boiler feed regulation. With it on the job day and night, you feel no anxiety; you know it cannot fail. The Vigilant is guaranteed to keep water level within ¼" of middle gauge.

There's another reason why you need the Vigilant. It will lower your coal consumption 3 to 17%.

Send for Engineers' Data Cards To-day.

Danger Without

The Vigilant to give positive protection is ever present. Let the feed water become high or low—a needless, costly accident too frequently results.

The Chaplin-Fulton Manufacturing Company
28 Penn Avenue - - Pittsburgh, Pa.

Positively Removes Boiler Scale and Prevents Further Formation

Users say Boico does that and more. It is the perfect boiler scale remover and preventive. It also saves fuel, oil and packing. Boico does not carry over in the steam, foam or prime. It never injures packings or valves.

Boico will rid your boiler of every bit of scale.

Free trial to prove it will.

MORE HEAT

from any grade of coal, coke or wood burned on Anti-Clinker Shell Bar Grates.

Copper Asbestos Boiler Gaskets

never blow out and never stick. Made of corrugated copper, with pure asbestos cord-filled corrugations. Use them and end all leaks in pipe lines.

Shell Bar Grates

Are built on a scientific air-draft principle. Fully 50% of their total surface is air space. They provide abundant air, and abundant air commands a perfect combustion, and a perfect combustion adds 25% more heat to the fuel gases and positively prevents clinker formation. Anti-Clinker Shell Bar Grates insure more heat from less coal. They're two grates in one; always clean; and they cannot twist or warp.

Write.

Shell-Bar Boico Supply, Limited

376 Dufferin St., Toronto, Canada

LESS COAL

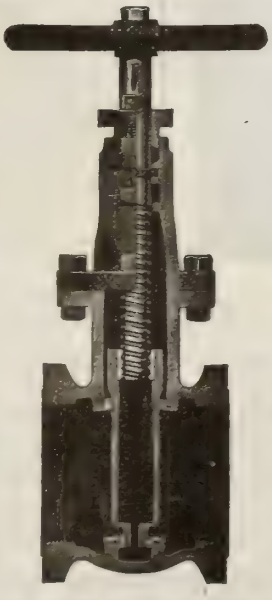
Because Anti-Clinker shell bar grates so intensify the heat that no fuel gas escapes in smoke.

Tip-It Patent Welding Process makes it possible to obtain tools with carbon shank permanently united to cutting tip of high-speed steel.

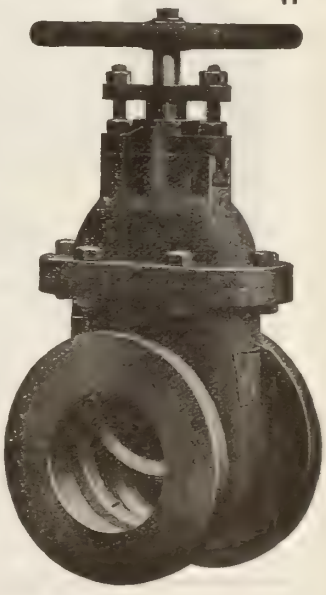
KERR

("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.



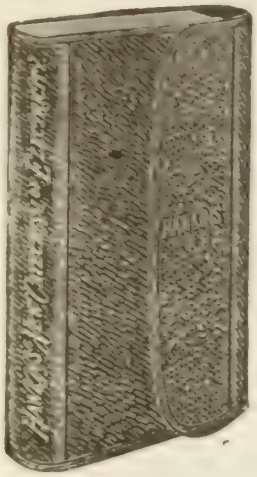
If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.



When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

Kerr Engine Co., Ltd., Valve Specialists **Walkerville, Ont.**

Books for the Engineer's Library



Hawkins' New Catechism of Electricity

It contains 550 pages with 300 illustrations of electrical appliances; it is bound in heavy red leather, with full gold edges and is a most attractive handbook for electricians and engineers. One-third of the book is devoted to the explanation and illustrations of the dynamo, with particular directions relating to its care and management—$2.10 post paid.

Engineers' Examinations

By N. Hawkins, M.E.

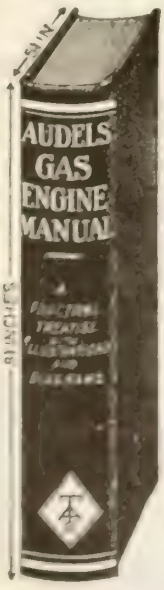
It presents in a condensed form the most approved practice in the care and management of steam boilers, engines, pumps, electrical and refrigerating machines, with examples of how to work the problems relating to the safety valve, strength of boilers and horse power of the steam engine and steam boiler.—$2.10 post paid.

Steam Turbines

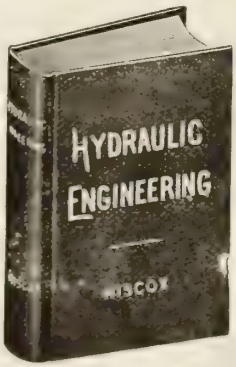
By Leland.

A reference work on the development, advantages and disadvantages of the steam turbine; the design, selection, operation and maintenance of steam turbine plants and turbo-generators. 135 pages. Illustrated.—$1.00.

Audel's Gas Engine Manual



A practical treatise relating to the theory and management of gas, gasoline and oil engines, including chapters on producer gas plants, marine motors and automobile engines.—$2.00.



Hydraulic Engineering

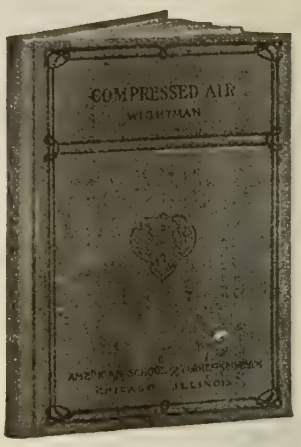
By G. D. Hiscox.

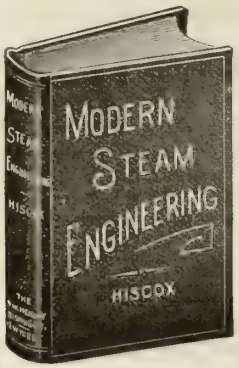
This comprehensive book of Hydraulics written by an experienced engineer, is a practical treatise on the properties, power and resources of water for all purposes, including the measurement of streams, the flow of water in pipes or conduits; the horse-power of falling water; turbine and impact water wheels; wave motors, etc. All who are interested in Water Works Development should have a copy. 320 pages, 305 illustrations. Price $4.15 post paid.

Compressed Air

By L. I. Wightman, E.E.

A reference work on the production, transmission and application of compressed air; the selection, operation and maintenance of compressed air machinery; and the design of air power plants. Illustrated.—$1.10.





Modern Steam Engineering in Theory and Practice

By Hiscox.

This book has been specially prepared for the use of the modern steam engineer, the technical students, and all who desire the latest and most reliable information on steam and steam boilers, the machinery of power, the steam turbine, electric power and lighting plants, etc. 450 pages. 400 detailed engravings.—$3.15 post paid.

Boiler Construction

By Kleinhans.

The only book showing how locomotive boilers are built in modern shops. Shows all types of boilers used; gives details of construction; practical facts, such as line of riveting punches and dies, work done per day, allowance for bending and flanging sheets and other data that means dollars to any railroad man. 421 pages, 324 illustrations, six folding plates.—$3.00.

Compressed Air, Its Production, Uses and Application. *By G. D. Hiscox, M.E.*

Comprising the physical properties of air from a vacuum to its liquid state, its thermodynamics, compression, transmission and uses as a motive power in the operation of stationary and portable machinery, in mining, air tools, air lifts, pumping of water, acids and oils and the numerous applicances in which compressed air is a most convenient and economical transmitter of power.—Price $5.15 post paid.

Boiler Accessories

By Walter S. Leland, S.B.

Assistant Professor of Naval Architecture, Mass. Institute of Technology, American Society Naval Architects and Marine Engineers. 144 pp., 80 illus. Cloth binding. A treatise giving complete descriptions of the various accessories of the boiler room and engine room essential to economical operation, such as evaporators, pumps, feed-water heaters, injectors, mechanical stokers, etc., with practical instruction in their use.—Price $1.10 post paid.

Positive Lubrication Assured

WHEN YOUR PLANT IS UNDER THE CARE OF THE

BOWSER ESTABLISHED 1885 **Lubricating Oil Circulating Filtering** **SYSTEMS** THE STANDARD ALWAYS

It is an everyday occurrence for some factories to have shut-downs once or twice a day, and the cause of this, many times, is improper lubrication. Dirt and grit gets into the oil during use. When such oil comes in contact with the bearings there is at once an unnecessary friction and "hot boxes" result—then shut-downs follow.

With the Bowser Filtration Systems shut-downs are avoided. More power is obtained from the engine and less wear and tear on the parts is assured. The dirty oil is taken by the system into its filtering compartment, where all the impurities are extracted. From this compartment the oil is returned to the clean oil tank ready for use again—as good as new. This system not only saves machinery, but it saves oil, as well. The refuse and dirty oil can be drawn from the chamber used to collect it and many uses can be found for it. This saving alone amounts to a sum worth considering.

Bowser Systems are built for any sized plant, to fulfill any requirement. The 6F shown below is especially adapted to plants whose engines are on ground floor instead of in basement, and where large volumes of water return with the dirty oil. Let us be your advisors in lubricant and power problems. Write to-day, explaining your requirements—no obligation on your part.

If any advertisement interests you, tear it out now and place with letters to be answered

Mr. Bruce's Counsel

SPECIFICALLY APPLIED, MR. BRUCE'S COUNSEL may be said to recommend that business men should read every week THE FINANCIAL POST OF CANADA, to inform themselves concerning current events in the realm of Canadian business and public affairs.

Frank E. Mutton, Vice-President of the International Time Recording Company, of Canada, wrote the following letter to the publishers of THE POST:

Attention, Editor:

Recently we sent you a subscription covering the delivery of THE FINANCIAL POST to each of our Sales Agents and Salesmen throughout Canada. This was prompted by the fact that, in our opinion, your paper is the best barometer in Canada of what is going on in the different industries from one ocean to the other in this country. Your paper contains information invaluable to any traveling representative of any firm.

(Signed) F. E. MUTTON.

Dated Oct. 12, 1917.

IN effect, THE FINANCIAL POST represents a Current Events Club, met weekly for the consideration and study of current affairs in Canada in relation to itself and the world at large. It represents the assembly of many, many surpassingly well-informed contributors who discuss intelligently, lucidly and proportionately, Canada's public and business affairs. No more stimulating and worth-while paper is published in Canada for the man who wants to be able to talk confidently, at the club, luncheon, board meeting, business council, public meetings, about Canadian public affairs.

THE price, $3, is nothing to the man who really wants to know. Three dollars spent for knowledge that multiplies a man's power and pleasure and satisfaction is a small, small sum to pay. We make our appeal for subscriptions to men who really want to know and who will take time each week-end to read profitably.

If you are willing to give this time, prove it by signing and mailing the coupon below

Talk Current Events

A Talk by H. Addington Bruce, Author of "The Riddle of Personality," "Psychology and Parenthood," Etc.

WHAT do you know about the doings in this great world wherein we live?

Do you try to form a really intelligent and well-considered opinion regarding events the world over?

Do you ever discuss their significance with friends and neighbors?

If asked what you think of any particular event, you are perhaps ready with an answer. Is your answer anything but a snap judgment, determined by prejudice rather than by reasoning analysis?

I put these questions not to be disagreeable, but because, if necessary, I want to spur you to appreciate the value that there is in discussion of current events.

Many people, fortunately, appreciate its value instinctively. Perhaps you are one of these. Many others are beginning to appreciate it.

This is shown by the growing popularity of clubs and classes on current events.

Only a few years ago such clubs and classes were almost unheard of. To-day most of our bigger cities have half a dozen of them or more.

In one city—Boston—a talented woman of my acquaintance draws an income of thousands of dollars a year from her leadership of current events classes.

Other men and women have similarly discovered that interest in current events is increasing so rapidly that they can well afford to organize classes like those conducted by the Boston woman.

Still, there remain many people—thousands of people—who never discuss current events. Many thousands more discuss only such events as come under the headings of "crime," "the theatre," and "sports."

These are the people I want to reach. They are the people I want to rouse to recognition of the practical helpfulness they will find in discussion of current events in general.

Current events clubs and classes might well be organized in every neighborhood, with weekly meetings to take up the outstanding happenings in international affairs, national politics, literature, art, music, science and industry.

Regular attendance at, and active participation in, these meetings will prove to be an education in itself.

It will enlarge the mental horizon and broaden the moral sympathies. By disciplining the mind to active thought it will raise the level of workaday efficiency.

It will make for a more alert, a more conscientious citizenship. It will give zest and color to a life which perhaps has hitherto been pathetically drab.

Unsuspected powers will be awakened With a better grasp on the realities of life, the whole personality will expand.

One evening a week is certainly not too much to give to a discussion of the day-to-day developments in our wonderful world.

It may mean doing without an evening at cards or at the musical comedy, or at the dance hall. But this, after all, is not a terrible sacrifice.

And from the occasional talk over current events will come more profit than could possibly come from any number of evenings spent in card-playing, dancing, or listening to musical comedies.—Reprinted from the Toronto Daily Star.

OLD "EXPANSION" AND "CONTRACTION"

can not get the JEFFERSON seat-ring loose

Straining and pulling to their utmost these forces are unable to even loosen the brass seat ring of a

JEFFERSON UNION

That's because it is put in right—scientifically.

First—the ring is a section of drawn brass tube—much superior to a cast brass ring.

Then it is embedded—under enormous pressure, into a recess until it is practically a part of the malleable casting itself.

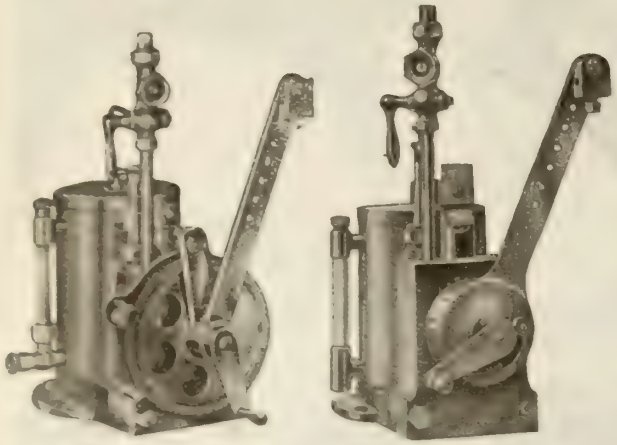
And this recess is back away from the runway and the contents of the pipe. Here lies the secret—the reason that contraction and expansion are unable to dislodge it and cause wire drawing and eventually leakage.

The other features of the Jefferson are unusual too.

The book "Unions" gives them all. Shall we send you a copy?

Jefferson Union Company, Lexington, Mass.

The Rochester Automatic Force Feed Lubricators



Ratchet Drive Pattern — Clutch Drive Pattern

Force feed lubrication is acknowledged to be the only correct method for lubricating the cylinders of all types of engines, pumps and air compressors, so that there is no need for any argument in its favor.

We recently received an unsolicited testimonial from the Chief Engineer of an Ontario Municipal plant in regard to a Rochester Lubricator. This is extremely unusual—if we were manufacturing patent medicines, unsolicited testimonials would be expected, but seeing that we are engineers, whose business it is to manufacture Pumps, Elevators, and Steam Appliances generally, why, a testimonial, especially one like this is something to be proud of.

This Engineer goes on to say:

. . . . . "I admire the Rochester Lubricator from the standpoint of simplicity, reliability, excellence of workmanship, and good materials. . . . suffice it to say, I know a good thing when I see it, hence I would not have ordered ANOTHER Rochester had it not been a satisfactory lubricator."

Note he says "another," and he tells us that this "other" has been in use for **twelve years and still going strong.**

It's too bad that we are unable to print this engineer's name and official capacity—he objects to publicity. We have it on file at our head office for reference, if necessary.

After all, this is only another proof of the excellence of our products.

JOHNS-MANVILLE Refractory Cements

JOHNS-MANVILLE SERVICE COVERS THE CONTINENT

An economical means of speeding up the boilers

IT'S an accepted axiom of good boiler practice that rapid combustion at high temperatures improves boiler economy.

But increased temperatures shorten the life of ordinary settings. The fire clay used as a mortar or bond cannot withstand high furnace heats; and in addition it squeezes out at joints when the brickwork expands. This leads to air leaks and incomplete combustion, and the boiler must be shut down every so often for setting repairs.

Johns-Manville Refractory Cements enable you to increase furnace temperatures because they are specially compounded for high temperature service. They cushion the fire-brick, absorbing expansion and contraction without displacement, and they hold their strength. A mortar of "No. 26" or "No. 31" Johns-Manville High Temperature Cement for the bond, and a wash-coating of "No. 32" over the inner face of the setting—that's what will insure tight walls and fewer shut-downs. Just give us a chance to prove it.

The CANADIAN H.W. JOHNS-MANVILLE CO., Ltd.

MONTREAL TORONTO VANCOUVER WINNIPEG

Canadian Association of Stationary Engineers

Incorporated May, 1887 — Incorporated at Ottawa, June, 1917

An organization having as its aims and objects:—

To promote the knowledge of its members in the art and science of Steam Engineering.

The dissemination of information beneficial to the members of the association in the discharge of their calling.

To further and protect the interests of competent engineers, and receive such as members of this organization.

To secure, through proper legislation, the greatest security in operation of steam plants.

To assist unemployed members to secure positions.

To maintain freedom of action between employer and employee.

The members of the Association subscribe to the above in the full belief that ability and knowledge of one's profession are necessary to insure the highest degree of success.

Labor Study Energy

These three essentials have been responsible for the success of the world's greatest men. They are no less essential for yours. We cannot all become great, but this fact does not lessen the necessity for the exercise of these essentials in our individual occupations. Cool, calm, calculating judgment characterizes the successful power house operator of to-day. The demands on the engineer of to-day are many, and the obstacles in his path are great. To assist in the overcoming of these and help the accomplishment of great works, material, moral and educational, is the desire of all our members.

The benefits accruing from association with members of his fraternity, the opportunity to benefit by their experience, and the inspiration to greater effort by reason of their success render membership in this association indispensable to all progressive engineers.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

J. H. HALE, General Secretary, C.A.S.E.

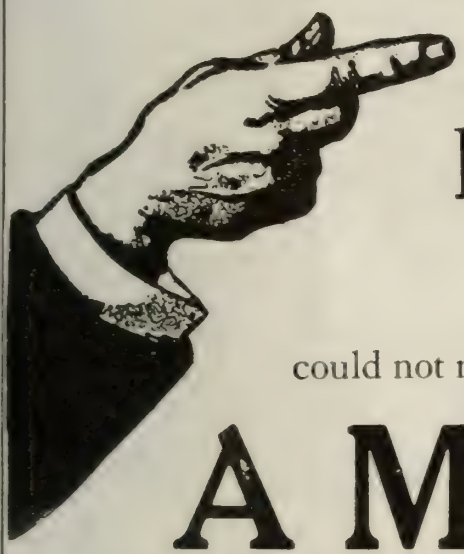
If it were other than Flawless Back Leather

Genuine British Oak Tanned



Even D. K. McLaren's Leather Belting

could not maintain Positive Grip at a belt speed of

A Mile a Minute

But you can depend on D. K. McLaren's Belting *retaining* its Positive Grip at a speed much greater than a mile a minute.

D. K. McLaren's Belting is made from leather taken from the centre of selected hides. It's the nearest to stretchless belting of any belting made.

Pulling greatest loads at greatest speeds never reveals "soft places" in McLaren Belting, for the good reason that shoulder, neck and belly leathers are never used in McLaren Belting. Nothing is used but the flawless back—*the heart of the hide.*

And McLaren's Genuine British Oak Method of Tanning gives to the finished McLaren belt really marvelous toughness, greatest pulling power and literally slipless grip.

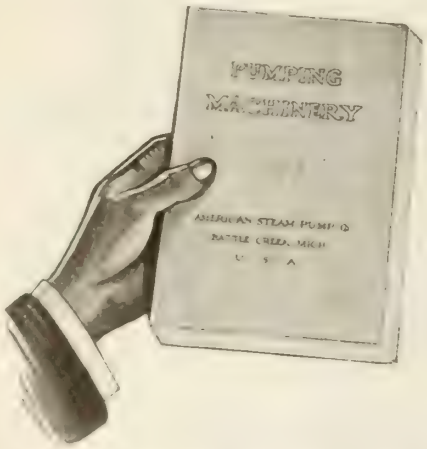
MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compressors



This book should be in the hands of every pump user. A postal will bring your copy promptly

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction*. Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under any unforeseen strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satisfactory operation, but practically *eliminates expensive shut-downs*. Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring oiled bearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

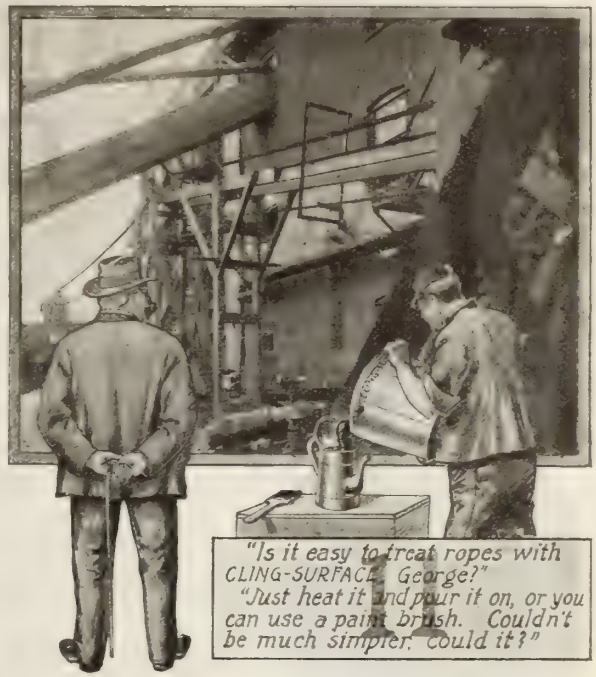
Babbitt Steam Specialty Co.
NEW BEDFORD, MASS.



"Is it easy to treat ropes with CLING-SURFACE, George?"
"Just heat it and pour it on, or you can use a paint brush. Couldn't be much simpler, could it?"

Some of the largest manufacturers of transmission rope not only use CLING-SURFACE on their own drives, but recommend it to their customers.

This proves its dependability, for these manufacturers, by recommending it, not only bank on CLING-SURFACE for the safety of their ropes in their customers' hands, but stake their own reputation as well.

But the best way for you to prove that this semi-liquid rope preservative, which contains no sticky or injurious materials, will quickly and easily preserve and waterproof your drives, will be to accept a can for 60 days' trial. It is understood that this is not to be paid for unless you are fully satisfied.

So write us now, or send for our Rope Folder P384.

Remember, use CLING-SURFACE and you won't need belt or rope dressings.

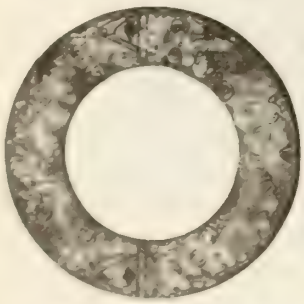
Style No. 200

High Pressure Packing will give reliable and efficient service without injury to piston rods, because it is thoroughly lubricated throughout every fibre, and the material, design and workmanship are unequalled.

Style No. 446

Medium Pressure Duo is a combination of high pressure and diagonal rings put up in sets to exactly fill stuffing box. The diagonal rings adapt themselves automatically to rods not running true, while the high pressure rings bear the brunt of the pressure and heat at bottom of stuffing box.



Style No. 950

Style No. 950 Gaskets are cut from Superheat Sheet Packing, which is made of the best quality of long fibre asbestos, built up under tremendous pressure, thus securing great tensile strength. They are not affected by extremely high temperatures, and being of a tough, non-vulcanizing material, do not need following up after being applied.

Greater Gripping Power

"Spiro" couplings are being used all over the United States and Canada, because their gripping power is 50% greater than any other coupling. The tightening of the bolts compresses the spiral slotted sleeve, and it grips the full surface of the shaft firmly. This sure grip eliminates any danger to your employees and helps safeguard your plant from shutdowns.

They are simple in construction, there are no keys to come loose or make quick removals difficult. Send for the "Spiro" Catalog, it's full of information concerning power appliances.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914 With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

STARRETT HACK SAWS CUT QUICKER LAST LONGER

The Utmost in Hack-Saw Thrift

Hack saws don't cost much—but they can waste much.

They waste mechanics' time if they are not suited to the metal or shape, just as a cross-cut saw wastes time when used as a splitting saw.

Again they waste time if they dull quickly or snap too readily. The

Starrett Hack-Saw

is characterized by the simple phrase—Cuts Quicker—Lasts Longer. They stay sharp because made of tungsten steel with teeth milled accurately and hardened just right—they cut rapidly when proper selection is made for the job.

What numbered saw to use is shown in Catalog No. 21CD. Send for it and consult page 208.

Live Steam Can't Escape

You don't want to lose live steam with fuel at the price it is—*and you can't* with this Anderson Steam Trap; for at least

3" of Water Lock the Valve

And neither sediment nor scale can possibly get into the valve. Strainer and Sediment Chamber see to that.

ANDERSON STEAM TRAP

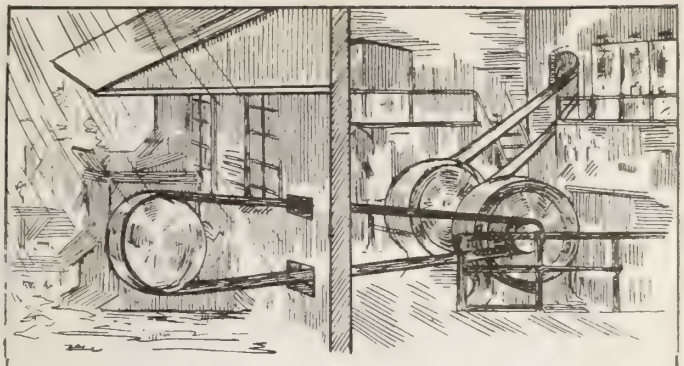
Model "D" lifts water against any back pressure 5 lbs. less than pressure at the trap. Both valve and valve seat are easily removed without breaking a steam joint or pipe connection. Every part is interchangeable. The Glass Water Gauge shows the Anderson Trap always properly working; still it's there as a safeguard.

No obligation for useful suggestions.

Write

The V. D. Anderson Co.

1935 West 96th St., Cleveland, Ohio



LANCO BALATA BELTING

A really waterproof belt—not just waterproofed. Works well on straight drives under all atmospheric conditions except those of extreme heat.

Joint can be made endless at our own plant.

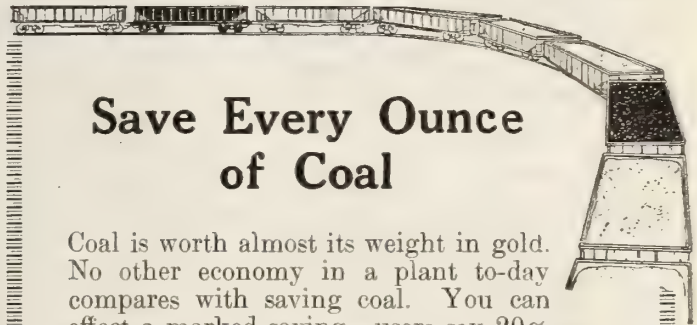
Does your belting man receive our monthly publication, "Belts"?

Sent free for the asking.

Federal Engineering Co., Limited

172 John St., Toronto

Save one out of five cars



Save Every Ounce of Coal

Coal is worth almost its weight in gold. No other economy in a plant to-day compares with saving coal. You can effect a marked saving—users say 20%—by utilizing every heat unit of your steam with the

Morehead

Back to Boiler

SYSTEM

By getting the value of every heat unit you do not have to use as much coal—and the efficiency of your plant is increased as well. There is a MOREHEAD SYSTEM that will fit your requirements. Let us give you further information and prices.

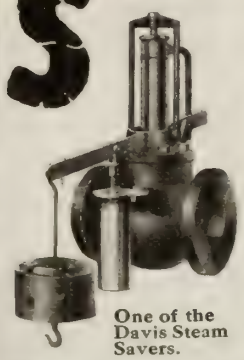
DAVIS

PRESSURE REGULATOR

Correct Pressure
and
Uniform Pressure
Insure
Efficient Operation—



One of the Davis Steam Savers.

And that means the Davis.

It is built like a pair of balance scales. The steam pressure inside is balanced by weights on the outside—the action is just as visible and accurate as the action of a pair of balance scales.

No spring pressure to vary, no packing to interfere with proper action, no delicate parts needing attention and adjustment.

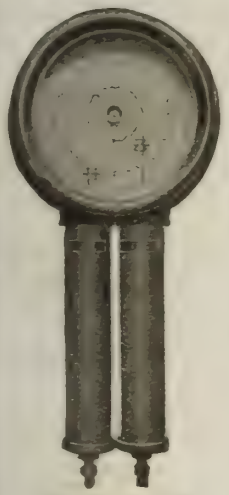
Simple and positive in action as the law of gravity—because it is controlled by gravity.

G. M. DAVIS REGULATOR Co
434 MILWAUKEE AVE., CHICAGO

UEHLING WASTE METER

COMBINED

CO_2 AND TEMPERATURE RECORDER



Record of CO_2 and stack temperature on one chart.

Does your fireman know how much fuel he is wasting? Do you know?

The **Uehling CO_2 Recorder** makes a complete 24 hr. record of your combustion efficiency and the **CO_2 indicator at the Boiler Front** holds the fireman responsible.

Get more **Steam** per pound of **Coal** and reduce your annual fuel consumption.

CO_2 Indicator for Boiler Front

Let us know the number and size of your boilers and coal consumed per year, upon receipt of which information we will be glad to send you full particulars.

Let us hear from you. We are pioneers in the manufacture of Indicators and Recorders for Power Plant purposes.

Send for our Bulletin No. 110.

Uehling Instrument Company

2008 Empire Building New York City

Niagara Power Co., Niagara Falls, N.Y. Floors protected with "R.I.W." Cement Filler and Cement Floor Paint.

"Dusting" Floors Means Injury to Machinery

The effects of "dusting" floors are far reaching. Not only does the concrete ultimately disintegrate, but meanwhile bearings, and other running parts pay a heavy toll in heating, dragging, and cutting down with grit. The rational remedy is

R.I.W. CEMENT FILLER & CEMENT FLOOR PAINT

REMEMBER IT'S WATERPROOF — REG. U.S. PAT. OFF. — PATENTED AS TO PORTLAND CEMENT FEB 27 '06

These products with a record of success behind them since 1905 penetrate the pores of cement or concrete, and harden the floor into a homogeneous surface. They are oil-proof, water-proof, wear-proof. Decorate as well as protect.

They prevent absolutely all dusting of cement or concrete floors of power plants, factories, garages and other buildings.

Valuable booklet sent on request. Address Dept. 59.

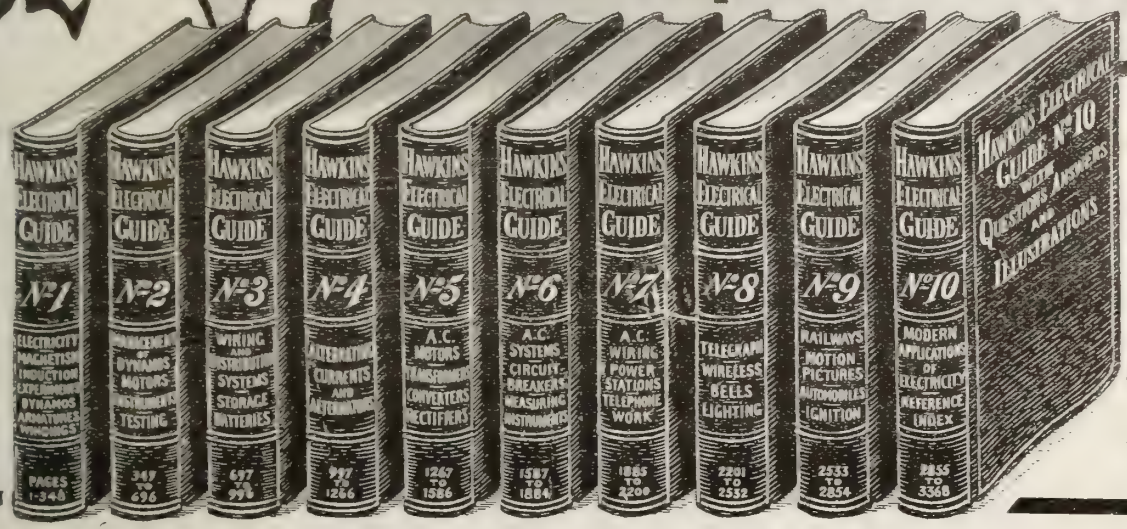
Every Electrical Man Wants These Books and we ship them for your inspection FREE



Flexible Covers — Handy Pocket-Size Volumes

10 Numbers — 3500 Pages — 4700 Pictures

$1 A Month — $1 A Volume

Just what you need to know to succeed in ELECTRICITY

EVERY electrician, every engineer, every mechanic should know about these wonderfully helpful instructive books, which give in plain words a complete working knowledge of electrical engineering in all its branches.

You run into some new electrical problem almost every day. The information you need to help you in your everyday work is in

HAWKINS ELECTRICAL GUIDES

These books place electricity at your finger ends. They cover every imaginable subject, principle, theory, problem, trouble, and way of doing things electrically. Every subject is indexed so that you can turn right to it. They are a study course and a reference guide in one, written in plain everyday language—no wasted words—only what you need to know—chock full of up-to-the-minute electrical knowledge. The guides are a complete course in electrical engineering. They will help you in every detail of the day's electrical work. You can't ask an electrical question that Hawkins Guides can't answer.

What Electrical Men Say

Helped Him Make Good.

"It is only right for me to recommend highly the Hawkins Guides, for they have been of the greatest assistance to me in placing me in my present position as Superintendent of Construction Department of one of Ohio's largest Electrical Companies. I would like to see every man have a set of Hawkins Guides."

Geo. Knecht, Columbus, Ohio.

In the Naval Electrical Dept.

"The Hawkins Guides are great help to me in the Naval Electrical Department, which they cover very thoroughly." C. J. Cornell, U.S. Receiving Ship, Brooklyn, N.Y.

Superintendent

"I am now superintendent of the Dunnville Hydro-Electric Systems, and Hawkins Guides were a great help to me in holding down a responsible position."

W. E. Swartz, Dunnville, Ontario.

Wireless Operators

"I have worked wireless for ten years—but I wish I had these books years ago, as they have saved me a great deal of trouble." H. Marshall. Steamer M. & B. No. 2, Walkerville, Ont.

Pocket-Size Flexible Covers

The books are small enough to slip into your coat pocket—handsomely bound in flexible black covers.

You can carry each volume with you until you have mastered its contents. 3,500 pages of actual information and 4,700 illustrations. Once you see these books and put them into actual use you will never again want to be without them. Try it at our expense.

SEND NO MONEY

It will cost you nothing to receive these books—to look them over—ask them all the questions you can think of—use them in your work—study them—pick up some information that will increase your earning ability. We will ship you the entire set of 10 volumes entirely FREE.

This is a sign of our confidence in the guides. Pure gold does not object to being tested. Keep them for seven days and if you do not decide that you can't get along without them, return them to us and owe us NOTHING.

When you decide to keep them you only have to pay $1.00 down and remit the balance of $9.00 on the easy payment of $1.00 a month till paid for.

Use this coupon to get the books. It will pay you many times over.

THEO. AUDEL & CO.
72 Fifth Avenue New York, N.Y.

READ THIS PARTIAL LIST OF CONTENTS.

No. 1 Contains 348 pages. 388 illustrations. Electrical signs and symbols—static current electricity—primary cells—conductors and insulators—resistance and conductivity—magnetism—induction coils—dynamo principles—classes of dynamos—armatures—windings—commutation—brushes, etc.

No. 2 Contains 348 pages, 394 illustrations. Motor principles—armature reaction—motor starting—calculations—brake horsepower—selection and installation of dynamo and motors—galvanometers—standard cells—current measurement—resistance measurement—voltmeters — wattmeters — watt hour meters—operation of dynamos—operation of motors, etc.

No. 3 Contains 300 pages 423 illustrations. Distribution systems—wire and wire calculations—inside, outside and underground wiring—sign flashers—lightning protection—rectifiers—storage battery systems, etc.

No. 4 Contains 270 pages, 379 illustrations. Alternating current principles—alternating current diagrams—the power factor—alternator principles—alternator construction—windings, etc.

No. 5 Contains 320 pages, 614 illustrations. A. C. Motors—synchronous and induction motor principles—A. C. commutator motors—induction motors, transformers; losses, construction, connections, tests—converters—rectifiers, etc.

No. 6 Contains 298 pages, 472 illustrations. Alternating current systems—switching devices—circuit breakers relays—lightning protector apparatus—regulating devices—synchronous condensers—indicating devices—meters—power factor indicators—wave form measurement—switch boards, etc.

No. 7 Contains 316 pages, 379 illustrations. Alternating current, wiring power stations—turbines: management, selection, location, erection, testing, running, care and repair—telephones, etc.

No. 8 Contains 332 pages, 436 illustrations. Telegraph—simultaneous telegraphy and telephony—wireless—electric bells—electric lighting—photometry, etc.

No. 9 Contains 322 pages, 627 illustrations. Electric railways—electric locomotives—car lighting—trolley car operation — miscellaneous applications — motion pictures—gas engine ignition—automobile self-starters and lighting systems, electric vehicles, etc.

No. 10 Contains 513 pages, 599 illustrations. Elevators—cranes — pumps — air compressors—electric heating—electric welding—soldering and brazing—industrial electrolysis—electro plating—electro-therapeutic—X-rays, etc.

Also a complete 126-page ready reference index of the complete library. This index has been planned to render easily accessible all the vast information contained in the 10 electrical guides. There are over 13,500 cross references. You find what you want to know instantly.

Don't buy that New Electrical Apparatus Just Yet

WE can supply you with high-grade apparatus that has been slightly used and discarded through no fault of its own, at an **immense saving in cost.** For instance, in many cases we take over entire plants simply because of changed conditions such as increased capacity, change of system, etc.

EVERYTHING IS OVERHAULED AND REFINISHED BY US AND **GUARANTEED** AS GOOD AS NEW, BOTH ELECTRICALLY AND MECHANICALLY.

Our catalogs of offerings should be in the hands of every power plant superintendent each time they are gotten out, and it will be worth while for anyone interested in this class of power plant equipment to be on our mailing list to receive **all** offerings.

Nearly all of the principal power, lighting and street railway plants in the United States are our customers.

WRITE FOR OUR LATEST CATALOG of **Power House Equipment, Street Cars, Motors, Hoists, Compressors, etc.**

Continuously Efficient Service

on the most troublesome lines is obtained only thru the use of

Homestead
Quarter Turn
Valves

If you want to know what a real serviceable valve can do for you in your Plant, just try a "Homestead."

Homestead Valves will last several times as long as the ordinary valve and will save their own cost shortly after installation through eliminating wastes and leakages.

Thousands of satisfied customers daily testify to its efficiency and back up their belief in this money-saving valve by giving us repeat orders.

We will cheerfully demonstrate the superiority of the Homestead Valve by sending you one for trial.

Write to-day.

Engineering Specialties

CURTIS Water Pressure Regulator

The Economy of this Curtis Water Pressure Regulator (See Illustration) lies in the fact that it greatly reduces the cost of keeping plumbing in order — This by obviating the wear and tear of water hammer or concussion in pipes.

This regulator is warranted to maintain the pressure desired, **with perfect uniformity, regardless of any fluctuations of outside pressure.** The workmanship and material of the Regulator **cannot be excelled.** Trouble from rust or clogging **is entirely avoided.** Delivery of water into service pipes at any desired pressure **is guaranteed.**

Send for special leaflet and price list to the manufacturers.

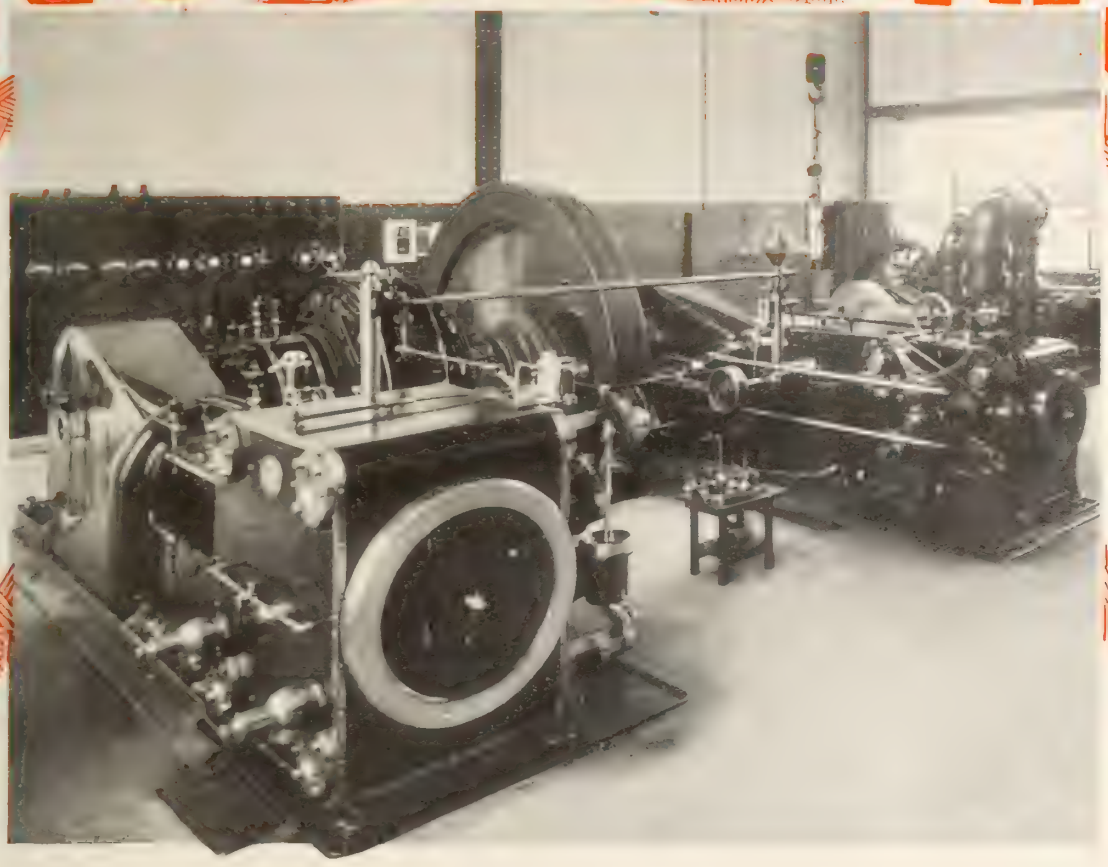
INGLIS ENGINES



An Inglis Installation

Canada's most prominent industrial concerns have shown a preference for INGLIS Engines. Illustration shows our Horizontal Cross Compound Heavy Duty Corliss Engine recently installed in the new plant of the Canadian Kodak Company, Mount Dennis (near Toronto), Ont.

Cylinders are 18 in. and 30 in. by 30 in. stroke, running at 150 r.p.m. Direct connected to a 300 k.w. Canadian Westinghouse 3-wire, 125-250 volt, d.c. compound wound computing pole type generator.

Engine operates on a steam pressure of 150 pounds, with 5 pounds back pressure. Valve Gear is operated by double wrist plates set for long range cut-off, the governor controlling both high and low pressure cylinders. Flywheel is 11 ft. in diameter and weighs 22,000 pounds.

Engineers and Boiler Makers—put your problem up to us; expert advice.

POWER HOUSE

A monthly newspaper devoted to the Generation, Transmission and Application of Steam, Gas, Electric, Air and Water Power; and to the operation of Refrigerating Machinery.

Published by The MacLean Publishing Company, Limited, 143-153 University Ave., Toronto

MONTREAL: Southam Bldg. LONDON, ENG.: 88 Fleet St., E.C. WINNIPEG: 1207 Union Trust Bldg.

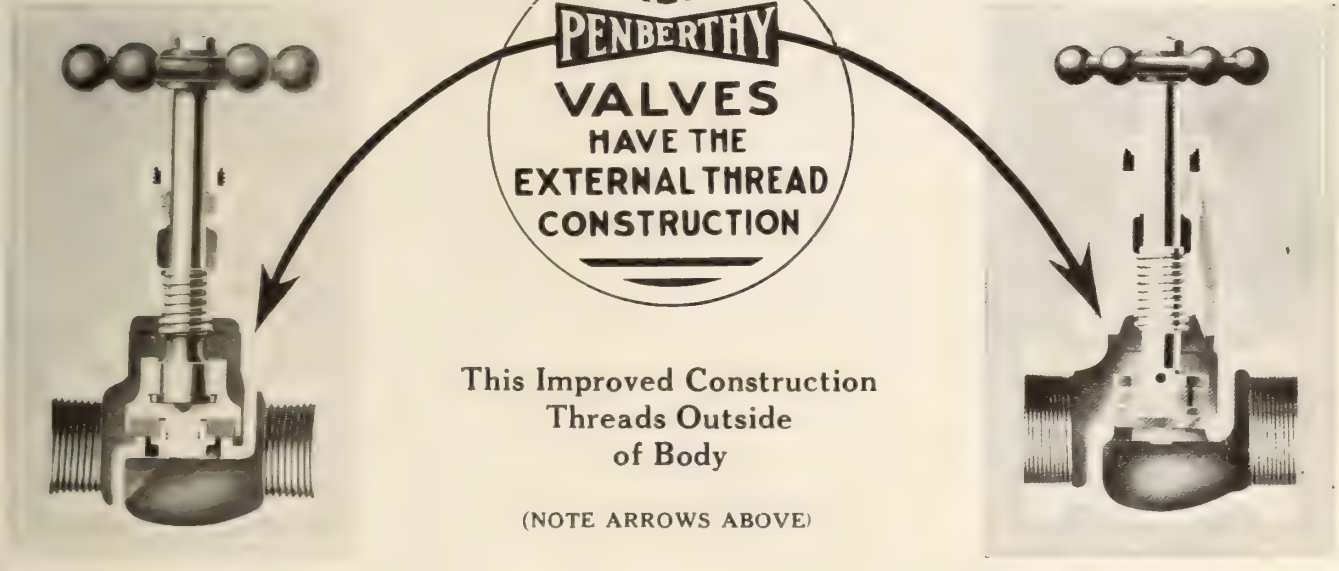
Vol XI—No. 2 Publication Office, Toronto—February, 1918 Published Monthly $1.00 per Year.

THE REASON WHY

TRADE PENBERTHY MARK **VALVES**

last longer and give so much **BETTER SATISFACTION** than other valves is due to their

SUPERIOR CONSTRUCTION



COMPODISK **REGRINDING**

Makes valve always accessible. Eliminates corrosion of threads. No corrosion prevents all strains in taking valve apart. Prevents spreading of body—causing a loose-fitting and unsafe bonnet. Makes a steam tight connection—no leaks. Permits of a more compact valve—consequently a stronger one.

For More Efficient Service Specify Penberthy

"ALL QUALITY VALVES"

Manufactured by

PENBERTHY INJECTOR CO., Limited, Windsor, Ontario

For Better Service in Mechanical Rubber Goods

THE United States Rubber Company, on January 1st, 1918, inaugurates an improved method of marketing in its *Mechanical Goods Division.*

This division includes Rubber Belting, Packing, Fire, Steam, Water, Garden and all other kinds of hose; Rubber Tiling, Mats, Matting, Jar Rings, Toys, Plumbers Supplies; Rubber Tape, Soles, Heels; Fibre Soles and hundreds of other rubber items.

Heretofore these goods have been marketed through subsidiary companies that for years have served all classes of industries, railroads, etc. These subsidiaries include:

Revere Rubber Co.
Peerless Rubber Mfg. Co.
Mechanical Rubber Co., Cleveland
Mechanical Rubber Co., Chicago
Sawyer Belting Co.
India Rubber Co.
Eureka Fire Hose Mfg. Co.

This plan will centralize the distribution of all these companies in one organization having branches and agents all over the country. This means quicker and better service everywhere for users of mechanical rubber goods.

The subsidiaries will continue to manufacture the brands, such as

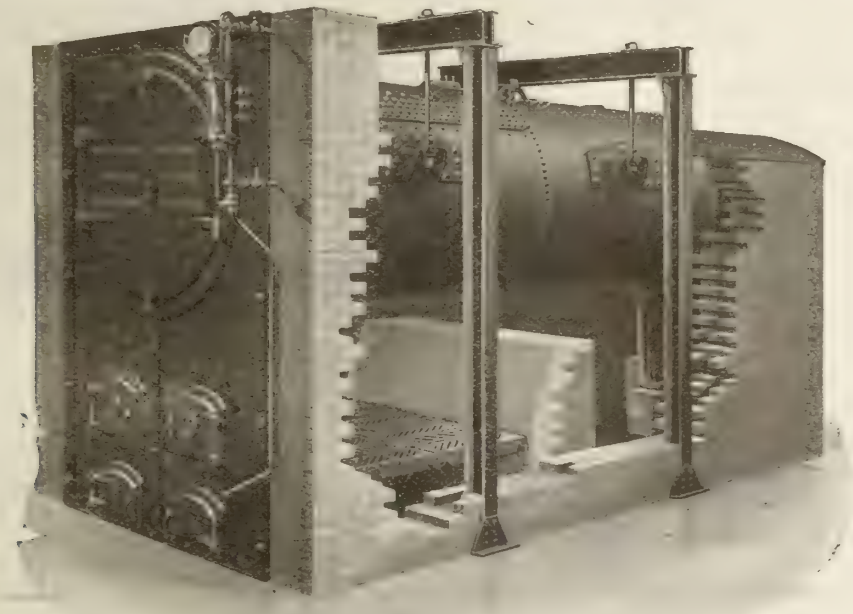
Rainbow Packing, Four Ace Belting, Giant Hose, Etc., Etc.

for which they are famous. The same high standard of quality and workmanship will be maintained. In addition the great seal of the United States Rubber Company, the hall mark of quality and value in rubber goods will identify these goods.

The assembling of all these well known brands in one selling organization makes the most complete line of mechanical rubber goods in the world. With distributors everywhere and factories in the large centers east and west we assure our customers the maximum in service and quality.

United States Rubber Company

BOILERS



WATEROUS Return Tubular Boilers are quick steaming, economical of fuel and absolutely reliable.

Power Boilers up to 165 H.P. Heating Boilers in sizes to 72″ x 16′—most standard sizes carried in stock.

We can supply brick or all-steel settings designed and dimensioned to give best results with whatever fuel you are using.

Boilers in stock for immediate shipment

Save Fuel

Anti-Clinker Shell Bar Grates

prove clinkers a needless waste of fuel. In many cases fuel gases must be subjected to as much as 25% more heat to prevent clinker formation.

This greater heat cannot be obtained without perfect combustion. And to obtain perfect combustion there must be an ample supply of air.

That's why 50% of the total surface of Patent Anti-Clinker Shell Bar Grates is air space.

They are always clean. Burning slack, coal, coke or wood: they never warp. Cost repaid in fuel saved. **Write.**

Boico Boiler Scale Remover and Preventive

Radically different from any "compound" you have used, and as much better. Without injuring packings or valves in the slightest, it will rid your boiler of every bit of scale and prevent further formation.

SEND FOR FREE TRIAL TO-DAY

Boico will not carry over in the steam, or foam or prime. Boico is good for your boiler—and your purse. You need it to save fuel

Copper Asbestos Boiler Gaskets never blow out and never stick. Made of corrugated copper, with pure asbestos cord filled corrugations. Use them and end all leaks in pipe lines.

Daniel's P. P. P. and Ebonite Packings for all Pressures. Only packing backed with scientific proof that it reduces friction. Long tests by Mechanical Engineers proved that P. P. P. saved 75% or more friction losses. Automatically regulates bearings on rod to requirements.

Galt Sprinkler Stokers Applied to Two 300 H.P. Water Tube Boilers

Are You Willfully Wasting Coal?

THE BUREAU OF MINES, WASHINGTON, D.C., SAYS:—

"The ordinary method of hand-firing boiler furnaces violates all the principles laid down for securing good combustion."

What Galt Sprinkler Stokers Will Really Do

(1) Effect a saving in fuel from 10% to 20%.
(2) Give a brilliant and perfectly level fire.
(3) Give practically smokeless combustion.
(4) Increase the boiler capacity to a large degree.
(5) Operate with natural, forced, or induced draft.
(6) Operate with less repairs than other stokers.
(7) Mechanically feed and uniformly sprinkle the coal continuously over the entire grate surface—with the fire doors closed.
(8) Burn bituminous, anthracite or lignite fuel.
(9) Eliminate the necessity of expert firemen.

Send for Illustrated Catalogues

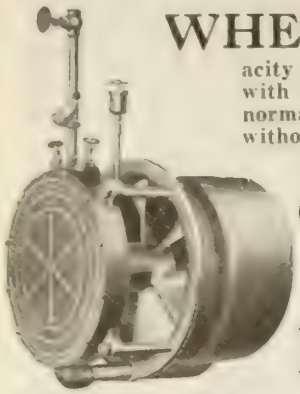
WHY put in another boiler



WHEN you can increase your present steaming capacity to 200 and in connection with stokers even 300% of the normal rating of the boilers without injury to the boilers by installing a

COPPUS TURBO BLOWER

You will have all the steam you want all the time Hundreds of satisfied customers will attest to this. No drop in steam pressure when a heavy load comes on, and you can laugh at the weather man, as you can dispense with him for your draft. Besides, the blower will pay for itself in a short time, as it will burn cheaper fuel.

Cut out this Ad., put your name and address on the margin, and mail to us. Without further trouble you will get all the particulars.

500,000 H.P.

In boilers equipped with Coppus Turbo Blowers in four years. The Coppus has replaced a great many other blowers, but no other blower has ever replaced a Coppus.

When Buying Thermometers

There's Just Three Things to Remember—

First, you must have accuracy and sensitiveness—

Second, durability is absolutely essential—

Third, the thermometer must be suitably constructed for the intended application.

Accuracy, sensitiveness and durability are absolutely guaranteed in

"Crescent" Thermometers

And with nearly seventy years of experience to our credit, we are qualified to properly interpret your needs.

Our Catalog P.H. 200 illustrates and describes "Crescent" Thermometers for every application. Also test thermometers, glass thermometers, etc.

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compressors

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction.* Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under any unforeseen strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satisfactory operation, but practically *eliminates expensive shut-downs.* Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring oiled bearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

Six Years in a Water Tank Didn't Feaze It

Six years as a float in an open water-cooling tank was the severe usage put to a sheet of Nonpareil Corkboard Insulation at the wholesale produce warehouse of Mr. Ben Ablon, Dallas, Texas. The illustration shows a piece of the sheet still firm, strong and dry inside; in fact, practically as good as the day it was put in.

Surely this shows that

Nonpareil Corkboard Insulation

For Cold Storage Rooms

is able to resist moisture—the greatest enemy of cold storage insulation. Cork is cellular in structure—not fibrous—and the pure cork granules, of which Nonpareil Corkboard is made, will not suck in moisture by capillary attraction. Furthermore, each one is coated with the natural waterproof gum or rosin of the cork by the baking process, giving an additional safeguard against the moisture of condensation. Nonpareil Corkboard is one of the best non-conductors of heat known, and, properly erected, it retains its efficiency indefinitely.

Send for the sample now. We will also include literature that will tell you all about Nonpareil Corkboard Insulation.

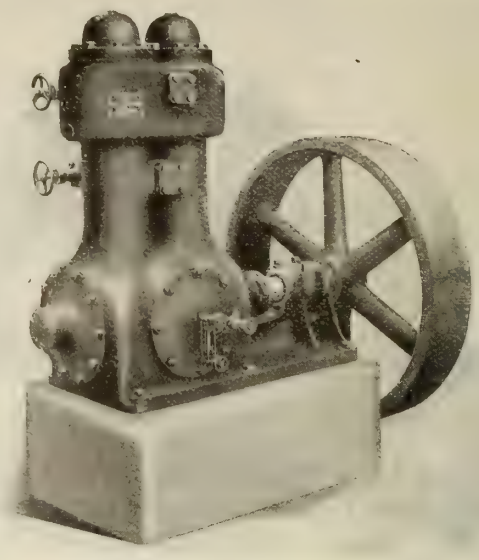
Armstrong Cork & Insulation Co., Ltd., 504 McGill Bldg. Montreal, Quebec.

Also manufacturers of Nonpareil Cork Covering for cold pipes; Nonpareil High Pressure Covering for steam lines; Nonpareil Insulating Brick for boiler settings, etc.; Nonpareil Cork Machinery Isolation for deadening the noise of machinery; and Linotile for office floors and residences.

Send for a sample of Nonpareil Corkboard and try this simple test for yourself. Break the sample of Nonpareil Corkboard in half and boil one piece for three hours. You will find at the end of this time that the boiling has caused little or no expansion, and that the granules are perfectly dry inside. Put other insulating materials to the same test and judge for yourself.

If any advertisement interests you, tear it out now and place with letters to be answered

Mechanical Refrigeration



is essential to success in many lines of manufacture, and YORK Products have played an important part in the development and expansion of these lines over the entire field.

We not only design and make a Refrigerating Plant suited to the needs of our customers, but all the details are handled by our own organization, which assures the best service possible.

YORK Refrigerating Machinery is the result of years of careful research, exhaustive tests, and the labor of experienced Engineers and competent Workmen; and for the Manufacturer who depends on the quality of his product for the continued success of his business, it is the logical equipment to buy.

The Economy of Business Paper Advertising

By H. E. CLELAND, NEW YORK

Awarded the Higham prize at the convention of Associated Advertising Clubs, at St. Louis, June 1917. This prize is given annually to the one delivering the most constructive address in the fewest words.

(Continued from last month)

THE time is coming when the principle of intensive advertising will be universally recognized and followed.

Manufacturers of machines and material and equipment which are sold direct to the consumer in technical fields will advertise them in technical papers.

Manufacturers of merchandise sold through retailers will advertise in trade papers first and will no longer be lured into attempting to sidestep the dealer. They will do the first thing first.

Manufacturers of merchandise selling to the general public will establish consumer demand (after distribution has been properly taken care of) by the zone system, using newspapers and outdoor advertising.

Advertisers to the general public with a thoroughly established distributing system will use newspapers and national mediums of many different kinds.

And advertising will reach the high plane that it is destined for only when all advertising men place their business along these lines, and only when the salesmen of different branches of advertising recognize that predatory invasion of the other man's field is the deadliest way to destroy confidence in all advertising.

We cannot force the super-tax of advertising extravagance upon the manufacturers of the world without eventually paying for it ourselves.

No wise salesman knowingly overstocks a dealer. No wise manufacturer of machinery ever recommends the use of his machine in order to make a sale if that machine will not fit the consumer's conditions. No up-standing and honest and far-seeing man will make a contract that does not benefit his customer as well as himself.

Advertising men must follow these methods or kill the goods.

Therefore, advertising men will advocate the use of mediums that present the utmost in efficient economy for the advertiser.

Which means that for certain classes of services, machinery, material, equipment and merchandise, the business papers will be used to their fullest extent. They must be used up to but not beyond the line of their efficiency.

And the business papers must continue the practice that all of the worth-while of them follow now—they must decline advertising which is not in the business line of the paper. To do otherwise is to destroy the principle of the specialized publication.

For those things which "belong" in a business paper—but for no others—the business paper presents the most economical method of efficient advertising.

VIEW OF PETERBOROUGH CITY WATERWORKS FROM WEST BANK OF RIVER, SHOWING UPPER FACE OF DAM.

The City of Peterborough Municipal Pumping Station

By H. R. Armstrong*

Originally installed by a private company, the plant and distributing system of the City of Peterborough were purchased by the city in 1902 and have been managed by a waterworks commission since. The efficiency of the plant and excellence of service are testimony to the intelligent management and skillful design and operation.

THE city of Peterborough receives its supply of water from the municipal pumping station, which is situated on the Otonabee River about two and a quarter miles above the centre of the city. There a massive concrete dam has been constructed to develop the power which operates the pumps. This reinforced concrete dam not only impounds the water in the river for the development of power, but also serves as storage for the supply to the citizens. It is about 300 feet long, and was constructed in 1909.

The depth of water behind the dam is about 12 ft. and affords an available head at the water turbines of about 10 ft., the suction lift of the pumps ranging from 3 to 10 ft. Provision is made to draw water from the tailrace, when frazil ice causes trouble about the dam, or when the stream is low and it is desirable to conserve the water for power. When the water is drawn from the tailrace the suction lift is about 18 ft.

Site of Plant

The pumping station occupies the western end of the dam and is a substantial building of reinforced concrete framework with brick panels. Together with the dam it was constructed by the Bishop Construction Company, being designed by William Kennedy, Jr., consulting engineer, Montreal. It measures about 125 ft. long, by 40 ft. wide, is steam heated and electrically lighted, and is thoroughly fire-proof. It houses three sets of water-driven horizontal single-action triplex pumps, a Worthington centrifugal pump and an auxiliary steam pump.

Plunger Pumps

Two sets of the triplex pumps were installed in 1893 and are of massive construction. They have three plungers each 18 in. dia. by 30-in stroke, and are operated at 20 revolutions per minute when run at full capacity. Each set is capable of delivering 2,225,000 gallons per 24 hours. The plunger heads are connected to the crankshafts carrying massive cog-wheels which are driven by pinions from a horizontal shaft that transmits the power from the water turbines through bevel wheels. The water power is developed by vertical Samson turbines with 62 in. wheels operating at 66 revolutions per minute.

Thes pumps were built by the William Hamilton Co. of Peterborough and were originally installed in the old pump house a short distance up stream from the present one, into which they were moved on its completion. After nearly 23 years of continuous service they are practically as good as new, and the cost of maintenance is infinitesimal. Judging by their present condition, if not overtaken by obsolescence they will be running fifty years from now. Their massive construction and the fact that they are slow moving are the principal reasons for their small depreciation.

The third set was built in 1909 and is a triplex pump of similar construction. The plungers are 21 in. dia. by 30 in. stroke, and are driven in like manner to the others by a Samson vertical turbine, having a 68-in. wheel running at about 80 revolutions per minute. The bevel gear reduces the speed of the pump to 22 strokes per minute. This pump has a rated capacity of 3,000,000 gallons per 24 hour.

Centrifugal and Turbine Pumps

The fourth set is a 3-stage Worthington centrifugal pump, also driven by a Samson water turbine. The water wheels rotate at about 80 revolutions per minute, and by means of accelerating gear the pump is capable of being driven at about 640 revolutions per min. The delivery from the pump is rated at about three million gallons daily. This pump was built by the John McDougall Caledonian Iron Works of Montreal and was installed in 1909. The Samson waterwheels, to which all four sets of pumps are directly connected were built by the William Hamilton Company of Peterborough.

The fifth set is a DeLaval single stage turbine pump, driven by a 400 horsepower steam turbine which operates at 6,000 revolutions per minute under 125 pounds steam pressure, The pump is driven at about 1,385 revolutions per minute by means of the usual reduction gear. This pumping unit is split horizontally for the purpose of providing easy access to all parts. The suction is 14 in. dia. and the delivery 12 in. This pump is arranged to draw water either from above the dam with a suction lift of 3 ft. or thereabouts, or from the tailrace with a lift of about 18 ft. It is rated at six million gallons per day under a total head of 228 ft.

The condensing plant consists of a Schutte-Koerting multi-jet condenser and a DeLaval centrifugal pump work-

*Office of Industrial Commissioner, Peterborough, Ont.

ing under 35 ft. head at 2,200 revolutions per minute, and discharging about 700 gallons per minute. The whole is driven by a type T.A. steam turbine, the pump and steam turbine being built by the Turbine Equipment Company.

For Engineering Use

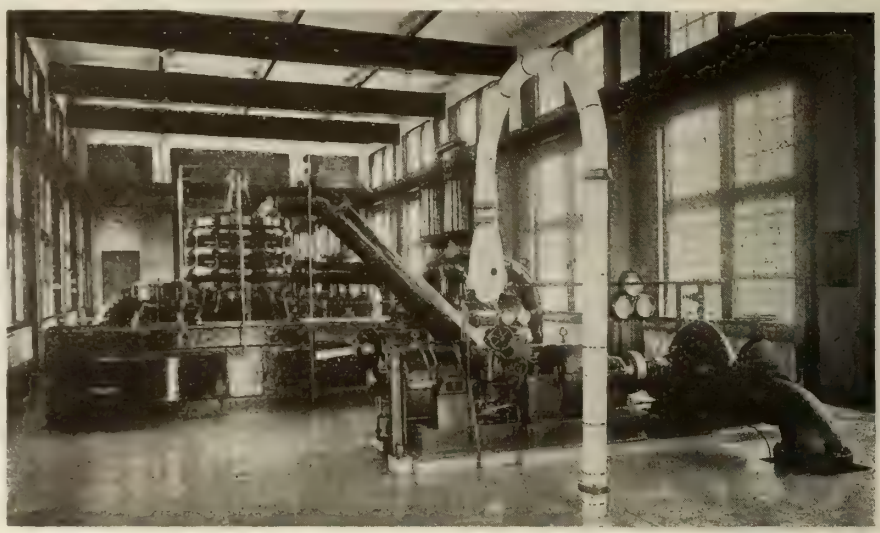
This fifth set was installed in 1915 as an emergency pump, to be used at times when the water-driven pumps cannot be used. Along with all other water power plants in this locality considerable trouble had been experienced from anchor and frazil ice. The pumps have been shut down on this account several times for considerable periods leaving the entire city in an inconvenient and exceedingly dangerous predicament. During the winter of 1914-15 this assumed a serious aspect, occurring three times with an average shut-down of 10 hours. After careful investigation of various schemes for mitigating this evil, such as steam-heated racks, covered forebay, etc., the commissioners decided to install a steam pump and have an entirely dependable remedy. A confirmation of their judgment was seen during the first winter after its installation. No less than five times was the unit called into service on account of the plugging of the water-wheels with ice. By its use an uninterrupted supply of water was delivered for domestic, commercial and protection purposes to the city during the winter.

Layout of Plant

The pumps are situated on the main floor of the building, and the pump-house is equipped with an overhead travelling crane carrying a hand operated 10-ton chain hoist.

There are two 100 horse-power horizontal return tube boilers for the steam unit, each 66 in. dia. by 16 ft. long, fitted with Cyclone shaking grates of 34 sq. ft. area. Induced draft is supplied by a fan driven by a 6-horse-power vertical steam engine, and by its use steam can be speedily generated. A 6 horse-power Foos gasoline engine is connected to the fan and is used to operate it when the boiler furnaces are being started.

The boilers are not heated until necessity arises. They are placed in a separate building to the south of the main pumphouse. The base of this is reinforced concrete with a brick superstructure and a laminated wood roof covered with 5-ply Barrett roofing. A Cochrane feed-water heater and the necessary boiler feed pumps are also installed in the boiler house, where there is storage for 75 tons of coal.



INTERIOR OF PUMPHOUSE LOOKING EAST. IN THE RIGHT FOREGROUND IS THE DELAVAL STEAM TURBINE AND PUMP AND BEHIND IT THE WORTHINGTON VERTICAL TURBINE PUMP.

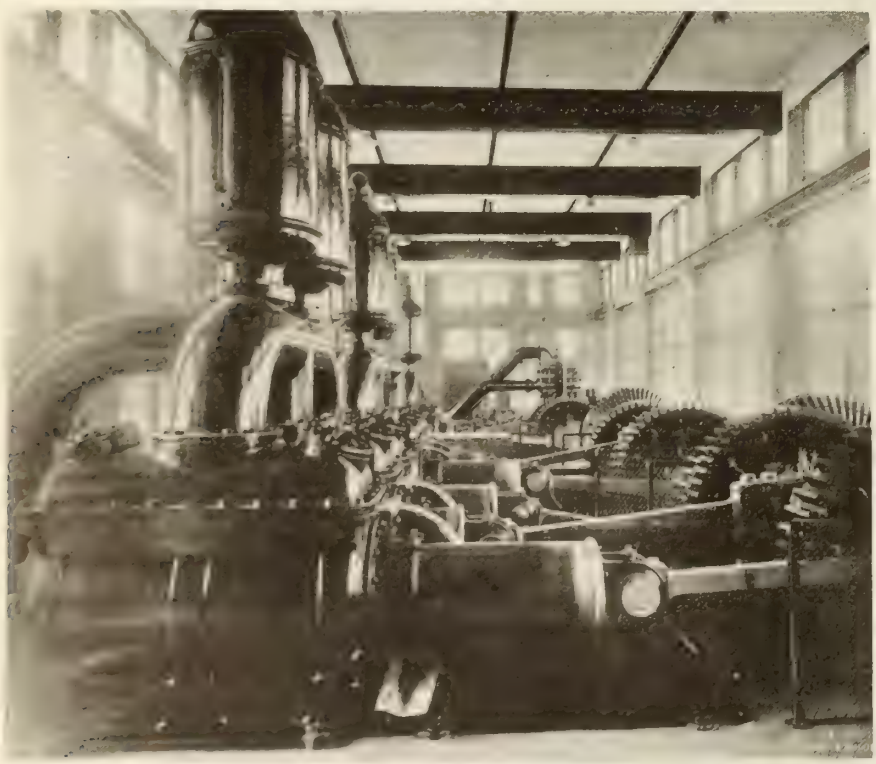
Pipe Arrangement

The water is drawn from the river through a 30-in. suction header and is discharged from the pumps through individual connections controlled by valves, into a 24-in. delivery main. In the delivery main is inserted a 10-inch Venturi meter to measure the quantity pumped. The pipe gallery is situated in the basement of the pumphouse running the length of the building. Two rows of pipes extend from end to end, one being the suction header and the other the discharge. The suction header is connected with each pump and receives the supply of water from an intake pipe extending above the dam. The discharge pipes of all the pumps are connected with the discharge header, in which is the Venturi meter for measuring the pumpage. The Venturi meter recording apparatus is in the office on the main floor, together with a self-recording Bristol pressure gauge. The meter is type M, manufactured by the Builders' Iron Foundry Company.

While on the average the river water at Peterborough is very good, at certain times of the year it becomes dangerously polluted, due to the sewage from the summer resorts in the lake above and also to the presence of river drivers on the river in the spring and early summer. As a result the Ontario Board of Health saw fit in the spring of 1916 to order the installation of a chlorinating plant as a precautionary measure. After investigating several methods and types of plants for the purpose a contract was let by the commissioners for a liquid chlorine apparatus to Wallace & Treiman, of New York.

Chlorinating Apparatus

The apparatus supplied and installed is known as type B, solution feed, automatically controlled equipment and was



INTERIOR OF PUMPHOUSE LOOKING EAST. THE TWO SETS IN FOREGROUND WERE INSTALLED IN 1893

placed in operation June 1, 1916. Owing to the variable character of the water the dose is adjusted to suit conditions. During the summer the ratio goes as high as 3 pounds per million gallons, but this is reduced as soon as the bacterial condition of the water warrants it. The average is about 1½ pounds to the million gallons. The chlorine costs about 25 cents per pound delivered at the pumphouse, inclusive of all charges.

PIPE GALLERY BELOW PUMPHOUSE. NOTE THE VENTURI THROAT AND METER IN FOREGROUND

The apparatus is connected with the Venturi tube in such a way that variations in the flow of the water are instantly followed by corresponding variations in the flow of the chlorine, so that the water does not become overdosed on some occasions and undertreated at others, as is often the case with manually controlled plants. This is accomplished by means of an arrangement whereby the Venturi throat above referred to not only measures the volume of water pumped, but also controls the operating of the chlorinating plant. The differential pressures at the inlet and throat of the Venturi meter are transmitted to the Venturi meter recorder and also to the diaphragm which controls the admission of liquid chlorine according to the varying quantity of water that is supplied.

The liquid chlorine is supplied in steel cylinders under considerable pressure and when it is decided what quantity of it must be used to sterilize the water it can be done easily by means of a glass gauge set against a graduated scale. Having noted the volume of water that is being registered by the meter, and adjusting the chlorinator scale to suit the required proportion of chlorine to be added, the differential pressures at the Venturi throat automatically regulate the chlorinator for other rates of flow. The liquid chlorine meets a small quantity of water in a glass and the resulting mixture is conveyed by a rubber pipe to the point of application on the intake pipe in the pipe gallery. In passing through the pumps it is thoroughly mixed with the main body of water. The chlorinator has been found to be compact and reliable, and has the great advantage that there are no moving parts to give trouble.

The necessary valves for the proper control of the different pumps are situated in the pipe gallery, together with the condenser and vacuum pump for the steam unit. The pump house is heated by means of a 30 horse-power horizontal return-tube boiler.

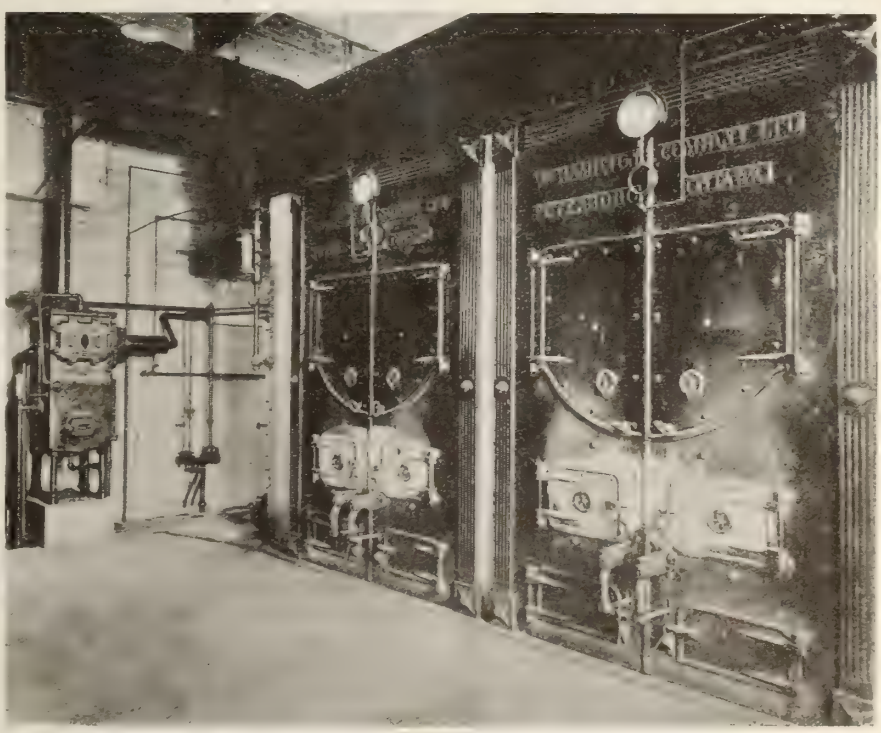
The pressure mains to the city consist of one 16-in. and one 18-in. cast iron pipe. These continue well within the city boundaries. The normal pressure at the pumps is about 70 pounds and the fire pressure is from 100 to 130 pounds per sq. in. There are about 44 miles of mains, ranging from 3 in. to 18 in. dia., all cast iron pipe. There are about 4,500 services. In 1916 the total quantity pumped was approximately 1,100,000 gallons, or an average of about 3,000,000 gallons per day. The average daily consumption of water in 1916 was about 136 gallons per capita. The cost of water, inclusive of all charges, averages about 4.95 cents per 1,000 gallons.

Late in 1917 a modern apparatus for the complete chemical and bacteriological analysis of the water was installed at the pump house.

Historical

The efficiency and completeness of equipment reflects the nature of the administrative body under which the Peterborough waterworks system has been developed and maintained. The waterworks were first installed in 1882 by a private company. In 1902 the plant and distributing system were bought by the city and put in charge of a waterworks commission. It now stands a splendid example of what intelligent commission government will do for the utilities of a city.

Mr. T. F. Matthews, the present chairman, has occupied that office since the formation of the commission. Mr. W. H. Moore, one of the present commissioners, has been a member of the commission since 1903. Mr. W. H. Hill was one of the original commissioners. He retired in 1914, and Mr. Robert Hicks, one of the present commissioners, was elected to take his place. Mr. R. L. Dobbin,



PAIR OF 100 HORSE-POWER "HAMILTON" BOILERS FOR SUPPLYING STEAM TO RESERVE UNIT.

B.A.Sc., is the waterworks superintendent, under whose supervision the auxiliary steam plant and the liquid chlorine plant have been installed. Mr. Wm. Kennedy, Jr., of Montreal, is the consulting engineer.

REPORT OF BOILER INSPECTION IN ONTARIO

THE Boiler Inspection Department of the Trades and Labor Branch, Department of Public Works for the Province of Ontario, completed its year on Oct. 31. The annual report prepared by D. M. Medcalf, chief inspector of steam boilers, shows that a large amount of work has been done by the department during the past year.

Work of Inspection by this Branch of the Department of Public Works, for the Fiscal Year Ending October 31, 1917.

GAS SUPPLY DEPLETED

THE investigation into the natural gas situation in Western Ontario before the Ontario Railway and Municipal Board at Chatham, Ont., last week, revealed the fact that the Tilbury-Raleigh gas field is being rapidly depleted, and that it will not be possible to supply all the demands being made on the producing companies for gas both for manufacturing and domestic purposes.

F. W. James, Superintendent of the Union Gas Co., in his evidence stated that with all manufacturing concerns cut off there will be a domestic supply good for some few years, but the supply is going down fast. He declared that for his company to cut off manufacturers and allow other producing companies working in the same field to send gas out for manufacturing would not materially lengthen the life of the field.

Gas from this field is sent as far east as Hamilton and Brantford by the Southern Pipe Line Co. and the Glenwood Oil & Gas Co., while the Union people send gas to Windsor, Chatham, Sarnia and a few smaller places in Essex and Kent counties. The Canadian Gas Co. also supplies gas for Wallaceburg and some for the Sarnia line.

It also develops that there are a number of contracts regarding the supply from the field and these will cause confusion. The Beaver Oil & Gas Co. had certain contracts, the Volcanic Oil & Gas Co. certain other contracts, the United Fuel & Supply Co. still others, and then the Union Oil & Gas Co. practically an amalgamation of all has still other contracts.

Contracts affect not only leases of land for production purposes, but also the delivery of gas to certain municipalities. It is contended that Sarnia, Windsor and Chatham each has original contracts with some one or other of the companies which give the right to all gas from certain sections.

The question which now arises is whether or not the original wells are exhausted and what the position of the Union Gas Co. is regarding these contracts, so far as wells are concerned which were drilled after the companies were all united.

CANADA GETS COAL SUPPLY

THERE has been much comment and speculation regarding how Canada would be treated under the restrictions recently placed on coal shipments by Dr. Harry A. Garfield, American Fuel Administrator. It was first thought that Canada would receive an allotment for the first three months of this year equal to the actual shipments during the first three months of last year. Later it was learned that licenses had been issued to American shippers for the export to Canada of only 40 per cent. of last year's actual shipments and that the Canadian Fuel Controller. C. A. Magrath, held licenses for another 40 per cent. of the amount, but these latter had to be approved by Dr. Garfield before they were valid.

Licenses for Coal

A letter enclosing licenses for specified quantities sent to American shippers by the American Fuel Administration clears up the situation. Licensees are requested to "note especially the following points:"

"(1) C. A. Magrath, Fuel Controller of Canada, Ottawa, by arrangement with the United States Fuel Administration, has been granted a considerable tonnage, and he has the privilege for the period mentioned to call on this Administration to issue permits to any shippers who apply to him.

"(2) All coal leaving a United States port of exit after midnight December 31st. 1917, will be reckoned as part of your alloted tonnage for the months of January, February and March, 1918.

"(3) Shippers are required to report to the Fuel Administration each shipment of coal to Canada at the time of its leaving the port of exit from the United States. Please give date of exportation and state quantities in tons and whether anthracite or bituminous (anthracite 2,240 lbs., bituminous, 2,000 lbs.).

"(4) No export licenses are required for individual shipments of coal, but the allotments as given in the enclosed permit limits the amount of coal you are at liberty to export to Canada during the period stated."

THE EKENBERG PEAT PROCESS

EXPERIMENTS on the treatment of peat by a modified Ekenberg process are being conducted at Chateauneuf, in the Departement Ille-et-Vilaine, Bretagne, France. According to a paper, published in the "Comptes Rendux" of September 3, and Octover 1 (errata), 1917, by C. Galaine, C. Lenorm and C. Houlbert, the peat is first compressed in presses of the Mabille or Aurep types to reduce the water in the peat from about 90 per cent. to 60 per cent.; the peat is then treated with superheated steam at 160 deg. C. for 25 minutes, and then either compressed again or at once dried, which is best done in special chambers, though air-drying may be applied. The product, which is called tourbon, still contains from 20 per cent. to 25 per cent. of moisture, but does not absorb moisture, as it would do if the cellulose in the peat had not been destroyed by the steam heat. The calorific value is stated to be raised by 10 per cent. over that of dried peat: the tourbon yields 61 per cent. of volatile matter, 36 per cent. of fixed carbon, and 3 per cent. of ashes. With suitable arrangement of the batteries of autoclaves and utilisation of exhaust steam, a heat efficiency of from 85 per cent. to 91 per cent. is claimed to be realised in this process, which can be worked throughout the year. The tourbon is fired directly, or sent to the gas works (with ammonia recovery), or converted into power gas for internal-combustion engines; the last-mentioned utilisation has so far proved most satisfactory elsewhere, we believe.

MARKET FOR PUMPS IN PARAGUAY

HENRY H. BALCH, United States consul at Asuncion, reports that there is a good market for small pumps in Paraguay. Inasmuch as there is no water-supply system for the city of Asuncion, which has about 80,000 population, or for any of the other cities or towns of the Republic, there is a constant demand for a limited supply of hand pumps, windmill pumps, electrical, and gas pumps to be used in wells for the purpose of supplying water to residences, business houses, public buildings, etc., in Paraguay. Aside from two breweries, three ice plants, three sugar refineries, some small bottling plants, and a very few other small plants which require pumps a little larger than those used by the average family, there is practically no market for any class except those used in supplying water from wells for ordinary family needs. The total value of all pumps imported into Paraguay in a year averages about $6,000, of which more than half represents imports from the United States. Germany hitherto has been the nearest competitor, followed by England.

The Preventable Waste of Coal in the United States*

By David Moffat Myers**

While asserting that the saving or waste of one-fourth of the coal consumption of any industrial plant depends entirely on the efficiency of the management, the author emphasizes the fact that this fraction of the consumption relates exclusively to the boiler plants and does not include the large economies possible in connection with its distribution and use.

As a means of far-reaching economy the Government of the United States should at this time apply intelligent and direct-acting efforts to the conservation of fuel at the industrial plants which are responsible for its greatest consumption.

The mining and distribution of the coal have been placed under the supervision of the War Coal Board in order more nearly to meet the crying needs in these directions, to use the railroad facilities more efficiently so that the present car shortage may be minimized and to apportion the coal in quantity and to uses deemed most expedient.

While this organized effort to bring about efficiency in the production and distribution of coal is being made, no parallel measures have been adopted to bring about a normal and practical efficiency in its use. The hundreds of large plants which are consuming fuel wastefully, in many cases more wastefully and carelessly than ever before, are directly and needlessly causing a large fraction of the existing car shortage.

Preventable Waste of Fuel

The preventable waste of fuel in the boiler furnace of one steel mill which I investigated amounted to 40,000 tons per year, which at $5 a ton would cost $200,000. This was a comparatively modern plant. The efficiency of boilers and furnaces in a 14-day test was 55 per cent. The load factor was unusually favorable to high efficiency and could readily be raised to 70 per cent or over. This is only one example, and there are many more extreme cases. In one hand-fired plant the evaporation was raised from 6 to 9 lb. in a few days of instruction and continuously kept close to this higher mark with the help of coal and water measurements which were inaugurated. The saving was due exclusively to instruction and consequent better operation.

The saving or waste of one-fourth of the coal consumption of any industrial plant depends entirely upon the efficiency of its operating management. Let me emphasize that this fraction of the consumption relates exclusively to the boiler plants, that is, the production of steam, and does not include the large economies possible in connection with its distribution and use.

For well-known reasons the boiler plant offers the more lucrative field for producing economies, and these with a minimum of alteration in physical equipment.

Under present conditions a plant which carelessly operates at an efficiency of 40 to 50 per cent. receives from the Government the same consideration in the delivery of coal as the one whose efficiency is 70 to 75 per cent. This obviously is unfair and wasteful.

The government hands over, say, 200,000 tons of coal a year to a plant owner, but asks for no accounting as regards its consumption, nor any questions as to the amount of steam it is made to produce.

There is no doubt that very important economies in the use of food have already been effected by educational campaigns. These economies are largely the result of educating the ultimate consumer. The requisite propaganda does not attempt to teach the intricacies of food chemistry or the complex action of the gastric juices.

TABLE I.—TOTAL COAL PRODUCTION, BITUMINOUS, LIGNITE AND ANTHRACITE, YEAR 1915.

	Net tons	%
1. Bituminous and lignite...	443,462,509	85.2
2. Anthracite	76,906,431	14.8
3. Total	520,368,940	100.0

The object of this paper is to open a discussion which, it is hoped, will ultimately lead to the formulation of definite fuel conservation recommendations, to forward these recommendations to the proper governmental authorities as an official communication of this society, and to offer to the Government the services of the society for the organization, furthering and, as far as possible, the execution of the plan which may as a consequence be adopted.

There are, I think, two plans of operation worthy of consideration. The one might be termed the autocratic method. This would involve use of authority to compel coal consumers to execute such measures of economy as the proper authorities might prescribe for any given case, limits to be set as to expense to the user. Such limits might be in terms of a percentage of his present yearly coal bill. Alterations should be directed chiefly, as previously implied, to purely operating improvements. Many objections would probably be made by consumers against this plan, but once in effect the majority would no doubt realize its pecuniary advantage to themselves. But its tendency may be too strongly opposed to democratic principles.

The other plan would be largely an educational one, in which patriotism and efficiency would furnish the motive forces required. The teaching must be accomplished with the utmost simplicity and directness. Above all it must be in such form as to be readily comprehended and applied.

The requisite information must reach the owners and managers of industries, and there must be simple instruction sheets for the engineers and firemen. The vital importance of daily accurate records of coal and water must be taught and information given regarding practical appliances for automatic measurements of both.

Blank forms might be sent in advance to plant owners in order to be advised by them, first, whether they would be willing to co-operate with a governmental organization offering to assist them in reducing their coal consumption, and second, to obtain such data as to size, type, equipment, operation and fuel consumption of the plants as would enable a classification that would permit a government board of experts to send such instructions as would include the information needed for any one class of plants.

This work would be very greatly aided by a staff of experts ready to visit plants when so requested by owners, and make investigations and recommendations and keep in touch with the progress of economies. Included in such a staff must be men intimately familiar with practical operating economies, whose duties would be the delivering of lectures or talks which should be planned so as to reach directly not only managers and owners of the industries, but also the chief engineers and firemen of the boiler plants.

The United States Bureau of Mines has for a number of years engaged in obtaining and disseminating scientific information regarding the mining and consumpton of coal, and the results of the work have been of great value to technical engineers who are able to use and apply it.

Six hundred million tons of coal was mined in the United States last year. It is predicted that 700,000,000 tons will be mined this year, and next year's production will likely be still greater. Of this quantity approximately 67 per cent, or 469,000,000 tons, will be burned for steam-making purposes on land, assuming the same percentage consumption for steam production as existed in the year 1915.

The saving or wasting of one-quarter of this coal, that is, over 117,000,000

*Presented at the annual meeting, December, 1917, of the American Society of Mechanical Engineers, New York.

**Consulting Engineer, New York City.

tons, depends on the efficiency with which we operate our boiler furnaces. If we actually saved by proper methods only 50,000,000 tons per year, this economy would result in freeing for other important service the use of 1,000,000 fifty-ton freight cars per year. The significance of such an economy may be realized when it is stated that the number of cars thus released for other service would be equivalent to 15 per cent more than the combined yearly coal-carrying capacity of the Baltimore and Ohio and Southern Railway systems; approximately equal to that of the Pennsylvania R.R. system on lines east of Pittsburgh, or 1 2-3 times the number of coal cars hauled by the Norfolk & Western. The direct saving to our industries would be $250,000,000 worth of coal per year, if figured at $5 per ton.

This saving would be $\frac{50,000,000}{469,000,000} =$

10.65 per cent of the coal now burned for steam production. It is impossible to state the present average efficiency of boilers and furnaces, but I have personally spent sixteen years of concentrated study in the investigation and improvement of steam and fuel conditions in factory power plants, and I have never visited a plant of this class where a saving in coal of at least 10 to 12 per cent could not easily be made. The poorer the conditions found the easier it is to make an attractive saving in fuel.

TABLE II.—PERCENTAGE DISTRIBUTION OF BITUMINOUS COAL AND LIGNITE PRODUCED IN THE UNITED STATES AND IMPORTED IN 1915, BY USERS

	%
1. Railroad fuel	28.0
2. Steamship bunker fuel—tidewater	2.0
3. Steamship bunker fuel—Great Lakes	0.3
4. Manufacture of beehive coke	9.3
5. Manufacture of by-product coke	4.3
6. Manufacture of coal gas	1.0
7. Domestic and small steam trade	16.0
8. Industrial steam trade	33.0
9. Exported	4.0
10. Steam and heat at mines	2.0
11. Special uses	0.1
12. Total bituminous and lignite	100.0

NOTE.—Imports were only a little over one-tenth of one per cent. and are, therefore, neglected.

No information is available for complete classification of the distribution of the anthracite, but it is estimated in report on "Coal in 1915*" from which Tables I. and II. are made, that 40,000,000 net tons of anthracite were used in 1915 for "heating households, apartment houses, hotels, and office, school and other buildings." This leaves about 27,000,000 net tons or 35 per cent. for industrial uses, principally steam making. If we eliminate households we may assume that 25,000,000 tons of the 50,000,000 tons are used for making steam, so that of the total 77,000,000 tons of anthracite, we may say that 52,000,000 tons, or 67.5 per cent., are used for [illegible]

*"Coal in 1915," by C. E. Sesher, published by the U. S. Geological Survey; Part A on production, Part B on distribution.

Table IV shows to what point the efficiency of a plant must be raised to obtain the saving of 10.65 per cent. upon which these economies are based. The poorly run boilers would of course be susceptible to the greatest improvements. Hundreds of boiler plants operate at no greater than 58.07 per cent efficiency, and it is a comparatively simple matter to bring them up to an efficiency of 70 per cent or higher. The latter would result in a saving of over 17 per cent of the coal.

If we do not limit our action to coal used for steam generation, but extend it to include economy with which the steam itself is utilized and applied, the predicted saving could be doubled, so that we might save 2,000,0000 fifty-ton carloads of coal per year. There is, for instance, widespread ignorance to a surprising degree in regard to the value of exhaust steam in heating and process work. The coal-consuming public should be taught that a heating system which requires 100 boiler horsepower may insert a steam engine between boiler and heating main and obtain nearly 100 mechanical or electrical horsepower in addition to the required heating for about the same consumption of fuel.

Steam plants are under the immediate management of chief operating engineers. The examination requirements for licenses in this profession call for practically no knowledge of steam and fuel economics. These examinations deal chiefly with matters of safety, repair and maintenance of equipment and neglect almost entirely the subject of coal economy. This is a very serious defect in our present system and is directly responsible for a large preventable waste of fuel.

The mining and distribution of our coal supply, the regulation of prices and the adjustment of financial and labor problems have already been placed under official administrative attention. But no parallel measures have been adopted looking toward reduction of waste in connection with the utilization of this coal.

Discussion of the Paper

Walter N. Polakov: The invitation to discuss the means and methods for reducing waste of coal is very welcome since all that has been said and done so far has failed to produce tangible results.

Last April I brought out the impending danger of a fuel famine and soon afterward the movement was on the way affecting at that stage only coal production, transportation and prices.

Being limited in its scope and nature, it did not embrace at that time the third group of my original recommendations concerning the use of fuel. My editorial in "Coal Age" of July 14 and articles in other magazines emphasized this paramount task "to start at once the movement for the efficient utilization of every available supply of fuel."

A couple of months later Mr. Garfield publicly admitted that the principal hope for a solution of the coal problem lies with the people themselves: "They must save every possible bit of fuel."

Saving may be carried out along two lines—either on the principle of German "Spar Kasse," inevitably limiting the industrial productivity and impairing the health of the people, or on the principle of more efficient utilization of fuel, producing more power and heat with less coal. Only this latter means of saving is to be considered.

The inauguration of efficient management of power plants cannot be accomplished overnight. It requires study in each plant of its peculiar conditions. It requires careful training of firemen and other employees. It necessitates an adequate stimulation of employees to continually maintain the highest degree of efficiency. To do it no capital investment is needed. It is not a matter of better furnaces, of mechanical stokers, or other cures preached by salesmen. It is a matter of knowledge and method.

There are already many plants that have reduced their coal consumption from 20 to 40 per cent for the same output by better organization of power-plant work. There is no need to here describe these principles and their results. "Task Setting for Firemen," a paper presented before this society in 1913, "Planning the Power Plant Work," a paper delivered before the Taylor Society, and numerous other contributions describe the nature of my work and fundamental principles more or less at length. Van H. Manning, Director of the Bureau of Mines, recently took the view advocated by me for years. Said he: "The immediate problem is a difficult one. We cannot scrap all out-of-date power plants. We must start by doing the best with what we have. We must begin saving coal at once. The problem is a peronal one. It deals with the human elements. We must reach the man with the shovel."

Mr. Myers presents for discussion two plans. The first one is unfortunately worded so as to create prejudice against it. It reads " . . . . the use of authority to compel coal consumers to execute such measures of economy as the proper authority might prescribe in any given case." It sounds Prussian. But is it? Does it mean imperialistic, arbitrary authority or an authority of an expert based on scientific knowledge of facts, similar to the authority of a doctor prescribing treatment?

TABLE III.—COAL USED ON LAND FOR STEAM PRODUCTION IN PERCENTAGE OF TOTAL PRODUCTION

Bituminous—	%
1. Railroads, item 1, Table II	28.0
2. Domestic and steam trade, assume only one quarter of item 7, Table II.	4.0
3. Industrial steam trade, item 8, Table II.	33.0
4. Steam and heat at mines, item 10, Table II.	2.0
5. Total bituminous	67.0
Anthracite—	
6. To steam making	67.5

Hence it may be assumed that 67 per cent. of all the coal produced is used for making steam on land.

To save 10.7 per cent. of the coal consumption necessitates the raising of any combined efficiency of boiler and furnace from that shown under Old Efficiency in Table IV. to the corresponding value under New Efficiency in the same table.

The strength of England, France and even the Central Powers is due to the co-operation in industries. Those who fail to render the service to the common cause are denied the privilege to mismanage their plants. True enough, this co-operation is regulated by the state

and at times compulsory as is conscription or commandeering of productive facilities or commodities. The voluntary co-operation for which we long will come only after the war as a result of new social readjustments. But we cannot wait. The problem is of to-day. To-morrow may be too late.

In other words we must create conditions stimulating voluntary co-operation even under individualistic regime.

The plan therefore means the abolition of privilege to waste fuel in inefficiently conducted plants, by giving priority in coal deliveries to those who prove that they use it efficiently.

At present a wasteful plant gets an excessive amount of coal, while the highly economical one stands an equal risk of being shut down for the lack of coal. If the efficiency is protected by priority, it will work also as a stimulus for the wasteful ones to find means to improve their methods and then ask for a new rating.

Such encouragement of efficient plants, rendering good service to the country and stimulating the inefficient to seek their salvation through the means beneficial to the country can be accomplished along the following lines:

Rating by experts (nominated by the national engineering societies and supported by public opinion and Government) of plants in the indispensable industries who are entitled, because of coal-saving methods in use, to the priority in coal supply.

Receiving of applications by the special service bureau of American Society of Mechanical Engineers, from the low-rated plants for assigning the expert help.

Serving the needs of such inefficient plants by offering services of recognized experts in power-plant management for direction of the work.

Organizing a staff of steam, electrical and combustion engineers, whose members will be assigned to carry out the work in the plants of the applicants under the direction and supervision of experts.

Charging for such services an adequate compensation to cover the expenses involved (salaries, traveling and office) but no profit.

Mr. Myers' second plan, "an educational one, in which patriotism and efficiency would furnish the motive forces required," is in my opinion doomed to failure for the following reasons:

Teaching efficiency by a correspondence-school method will accomplish little good, is incompatible with the professional dignity of this society and lacks the personal touch.

Endless variety of equipment, grades of fuel available, personality of men, nature of load, climatic conditions, etc., make the preparation of "simple instruction sheets for engineers and firemen" impossible and if made they are so general as to be useless. Failure of the Massachusetts fuel board in such an attempt is a joke among power-plant men in this section.

No instructions of real value could be given unless examination of the plant was made. Selling patent medicines curing all diseases ranks with fake only too often not to make one careful.

Keeping records, logs, etc., necessitates instrument equipment and measuring devices; all of this is good only when the data are used and interpreted by a trained man and this is done continually. Too many plants have no instruments at all; most of those that have keep them as ornaments owing to the lack of proper organization.

If the regular employees failed to secure high efficiency it is not because of the lack of "circularized education," but chiefly on account of lack of time to carry on investigations and tests, all the time being absorbed by routine duties; absence of instruments, facilities or encouragement; lack of experience in this highly specialized line of research work.

The education must begin with owners and managers, not with the firemen.

The very principle of "teaching" and "instructions" given to manufacturers and plant owners by the society is undemocratic and un-American. They do not want or need "to get something for nothing." Producing for the country but not without profit they can prefer to pay for what they get if the benefit is commensurate with the expenses.

"Educational" talks and circulars usually degenerate rapidly into debating societies, wasting time needed for deeds.

Any half-measures with good intentions falling short of accomplishing valuable results are dangerous as they chloroform the public conscience, creating a belief that something real is being done while there is little behind the words that make all content.

To sum up, the problem is to be solved by groups and individuals availing themselves through this society of services of those who know how more power can be gotten out of a pound of coal. There is no necessity to compel plant owners to improve their methods since in such a step lies their self-preservation. But there is an urgent necessity from the national viewpoint to conserve the fuel by preventing its waste by ignorance or indifference. The valuation of plant methods to establish ratings for priority in coal deliveries is therefore recommended.

Albert A. Cary: Mr. Myers endeavors to focus our minds upon this panacea in the statement that "the saving or wasting of one-fourth of the coal consumption of any industrial plant depends entirely upon the efficiency of its operating management," and this seems to be the text upon which the balance of his paper is founded.

To secure the desired conservation of fuels in such plants, Mr. Myers advises the services of the expert in operating management. Provided he understands his business, such an expert can undoubtedly secure desirable fuel savings; but results depend largely upon the co-operation he receives from the plant owners and their employees, as well as their willingness to equip plants with the needed apparatus and to use them continuously after the expert concludes his work.

TABLE IV.—INCREASE IN COMBINED EFFICIENCIES OF BOILER AND FURNACE NECESSARY TO EFFECT A 10.7 PER CENT. SAVING IN COAL

Old Efficiency Per Cent.	New Effciency Per Cent.	Old Efficiency Per Cent.	New Efficiency Per Cent.
44.67	50	62.54	70
49.14	55	67.	75
53.60	60	71.47	80
58.07	65	....	..

$$\text{Saving of coal with same output of steam} = \frac{\text{New Efficiency} - \text{Old Efficiency}}{\text{New Efficiency}}$$

$$\text{and increase of steam production for same coal} = \frac{\text{New Efficiency} - \text{Old Efficiency}}{\text{Old Efficiency}}$$

To illustrate, I will refer to the plant of one of my clients, the Tennessee Copper Co. By redesigning the furnaces in this plant and adapting them to the fuel used and by substituting machine-fired grates, they have since succeeded in obtaining the same amount of steam with but 64 per cent of the Jellico coal formerly used. This plant, when completed, was turned back to same management that it had before with no further instructions. There were installed facilities for continuously determining the weight of the coal, ash and water used as well as the analysis of the furnace gases.

In another large industrial plant a similar saving in coal was effected. This plant has an aggregate capacity of over 7,000 nominal boiler horsepower, divided into 22 units. It was formerly operated with hand-fired shaking grates for which machine-fired grates were substituted with properly designed furnaces. The plant is now being operated continuously at 150 per cent. rating and is using no more fuel than it formerly did when being operated at two-thirds of its present output. The boiler-room force required to operate this altered plant is less than half of the number of men formerly required. No change has been made in the management of this plant.

Proper furnace design and construction, flue and draft-producing equipment adapted to the use of the particular kind or quality of fuel used is the keynote of the question of fuel conservation.

Furnish the mason with complete instructions for "laying up" the brickwork and properly bonding the interior and exterior walls of the furnace so that the large difference in temperature between the two sides will not, by unequal expansion and contraction, rapidly destroy these furnace inclosures and so waste fuel by infiltration of air.

The selection of material used and its method of erection should never be left to the mason, as it is safe to say that fully 90 per cent of the masons erecting furnace settings are hopelessly un-

qualified to produce a proper setting. After equipping the plant with proper furnace settings which are adapted to produce the highest possible efficiency with the particular fuel available, the expert in operating management can come into the plant to instruct the men.

To meet the present emergency, I propose that the War Coal Board bring all the firemen in this country under its control by requiring them to take out United States licenses. The various state, county or municipal governments can assist them in this work. The applicants for these licenses must show some qualifications that would entitle them to hold such privileges, but it is doubtful whether it would be possible, at the beginning, to have all these applicants examined before qualified examination boards.

Future applicants should be required to pass an examination before such boards and qualify in a satisfactory manner before receiving their licenses. Any operator of a coal-burning plant (domestic plants, of course, excepted) who operates his equipment without a licensed fireman should be liable first to fines and finally to more severe penalties.

Each license should be issued for the applicant to operate in a definite, described plant and nowhere else. Should the fireman leave this plant for any good reason, rather than for incompetence, he can take his license to the proper authorities and have it transferred to another plant where he has found re-employment.

Should the fireman be found to be incompetent, his license should be revoked and future applications be denied.

Inspectors appointed by the War Coal Board might visit from time to time the various coal-burning plants, and should they find any of them using fuel wastefully, a notice should be served upon the owner. If this is not followed by prompt action to reduce or stop the waste, the fireman's license should be revoked.

The foregoing is proposed as a war measure.

Professor L. P. Breckinridge told of the methods used in Connecticut to conserve coal, stating that meetings were held to which the public was invited, to be told how to burn coal economically in house and power-plant boilers. Norman Reinicker believed that fuel economy was much more a matter of design than education of firemen. E. N. Trump emphasized the value of bonuses to firemen to give incentive for economical use of coal.

GAS FIRING AND REGENERATIVE SETTINGS

By T. J.

IN the earlier days of gas firing, as applied to retort settings, there were some rather vague ideas current as to the economy just effected. The saving of fuel consumption and the higher working temperatures attained in the retorts were often too hurriedly attributed to the recovery of waste heat. Waste heat is, of course, recovered, and returned to the setting in the preheated secondary air, but all the advantage does not lie merely with this recovery.

The advantages of gas firing as ordinarily practised are chiefly in three directions:—(1) The application of heat. High temperatures are generated in close proximity to the retort, and not as with direct firing at a considerable distance away, where much of the heat applied is in the form of much cooler and rapidly cooling convection currents of gaseous products. The study of flames may be applied with advantage to the question of gas firing of retorts, which is really a question of the application of flames. (2). The regulation of air. This can be accomplished to a very fine point so as to avoid the drop of available temperature due to the admixture of a large excess of air. (3). Regeneration or recuperation. Much heat is in waste products, i.e., gaseous products of combustion (mixed with air), which have passed the retorts and are on their way to the chimney. Any of the contained heat that can be transferred to the incoming air (usually the secondary air) is so much pure gain.

In Europe regeneration and recuperation of heat are used pretty much as interchangeable terms. In America recuperation is applied to the process by which (as in retort settings) the heat of the waste gases is transmitted through the walls of a flue and is given up to the air in an adjoining flue, while regeneration is there chiefly confined to the recovery of heat from heated chequer work over which the hot waste gases are first passed, and then by a change-over valve the incoming cold air is led over the same chequer work. Regeneration in this sense was tried on gas works, but its use was not long continued, though the same arrangement is successfully used on some coke-ovens, notably the Simon-Carves type.

Recovering Waste Heat

It is often too rashly assumed that all the heat taken to the combustion chamber by the secondary air of an ordinary retort is this recovered waste heat. It is usefully applied heat, but not necessarily all waste heat. Some of it may be initial heat. In cases where the secondary air travels are placed between the waste gas flues and the furnace, some of the heat in that air will undoubtedly be derived from the furnace. As the air is ceaselessly passing through these flues, and thus tending to cool them, this constitutes a drain upon the heat resources around the flues, and thus will certainly withdraw some of the furnace heat. Whether this procedure may be right or wrong may be open to discussion.

It is all to the good to get the secondary air as hot as possible; but no mistake should be made by considering the heat it withdraws from the neighboring furnace as recovered waste heat. It is abstracted initial heat, and its loss tends either to increase the fuel consumption or to lower the temperature of the producer gas. It may seem unnecessary to labor or even to mention the point, but the heat that can be produced from a given weight of a given coke is fixed and unalterable, whether the coke is burning direct to the carbon dioxide, as in direct firing, or first to the monoxide and then to the dioxide, as in gas firing. Still the idea lurks around in some minds that gas firing actually produces more heat from the fuel.

What gas firing really does is to transfer much of the heat production from the generator to the actual setting some 70 per cent. of it. In the same way the use of water on the fire bars, which when vaporized and passed through the furnace generates some water gas, does not furnish any new source of heat. Whatever heat is given out by its combustion exactly balances the heat abstracted in its formation. All that is gained in a thermal sense is the transference of heat from the lower part of the fire, where a high temperature favors the formation of clinker, to a high zone where it is more useful and less likely to entail harmful secondary effects, such as fusing the ash into clinkers.

WILL WOOD FUEL TAKE PLACE OF COAL?

DURING the current season, the unfortunate dependence of Canada on the United States for its supplies of coal has been brought into vivid prominence and, as a result, there has been much searching for possible substitutes. Naturally, wood was one of the substitutes to attract attention. The fuel value of good hardwood compares unfavorably with anthracite coal, a pound of such coal being equal to approximately two pounds of hardwood. For this reason, in markets that are far removed from sources of supply, wood is more expensive than anthracite, so long as the prices and available supplies remain as now.

The southern portions of Manitoba, Saskatchewan and Alberta have no large supplies of wood. Up to a few years ago, wood, cut locally, was used to some extent, but, with the gradual exhaustion of these supplies, the demand for coal is increasing yearly. The cordwood used in the Prairie Provinces comes from the Rainy River district of Ontario, southeastern Manitoba, the western shores of Lakes Winnipeg and Manitoba, the vicinity of Prince Albert, the Kootenay district of British Columbia and Minnesota.

These sources of supply are at a considerable distance from the centres of population, and, as cordwood is bulky, the long freight haul to market largely increases the price. Even in certain of the areas mentioned supplies of cordwood are becoming exhausted, and it is evident that, under present conditions of transportation, there is no likelihood of its being used to any greater extent than at present.—W. J. D. in "Conservation."

Emergency Repairs on Damaged Engine Parts

Special Correspondence*

Power house accidents involving damage to engines and boilers on a large scale are comparatively infrequent. In most cases they are pure accidents and the damage can be ascertained by ordinary inspection. The malicious damage sustained by the engines and boilers of interned German steamers had to be repaired rapidly, and the nature and extent of the damage, together with the successful repairs executed, possess instructive interest for all engineers in charge of steam plants.

ALL the damage done to 109 German ships by their crews, prior to their seizure by the United States Government when war was declared, has been repaired and these ships are to-day in service, adding more than 500,000 gross tonnage to the transport cargo fleets in war service for the United States.

There is evidence that a German central authority gave an order for destruction on these ships, effective on or about February 1, 1917, simultaneous with the date set for unrestricted submarine warfare and that the purpose was to inflict such vital damage to the machinery of all German ships in our ports that none could be operated for from 18 months to 2 years.

German Purpose Signally Defeated

This purpose has been defeated in signal fashion. In less than eight months all the ships were in service.

The destructive campaign of the German crews cunningly comprehended a system of ruin which they believed would necessitate the shipping of new machinery to substitute for that which was ruthlessly battered down or painstakingly damaged by drilling or dismantlement. There is documentary proof that the enemy believed the damage irreparable.

To obtain new machinery would have entailed a prolonged process of design, manufacture, and installation. Urged by the necessity of conserving time the engineers of the Navy Department succeeded, by unique means, in patching and welding the broken parts and replacing all of the standard parts which the Germans detached from their engines and destroyed or threw overboard.

Scheme of Ruin Shrewdly Devised

The mechanical evidence is that the campaign of destruction was operated on these ships for more than two months and that the Germans were convinced that they were making a thorough job of it. Their scheme of ruin was shrewdly devised, deliberately executed, and it ranged from the plugging of steam pipes to the utter demolition of boilers by dry firing.

When the United States Shipping Board experts first surveyed the ruin the belief was expressed that much new machinery would have to be designed, manufactured, and installed, making 18 months a fair minimum estimate of the time required. However, at the Navy Department, where the need of troop and cargo ships was an urgent issue, officers of the Bureau of Steam Engineering, having faith that the major portion of the repairs could be accomplished by patching and welding, declared it was possible to clear the ships for service by Christmas, and the last of the fleet actually took her final sea test and was ordered into service as a Thanksgiving gift to the nation.

Special Workmen on the Job

To accomplish this end the Navy Department secured the services of all available machinery welders and patchers, many of them having been voluntarily offered by the railroads.

Although explosives were not used in the process of destruction, the engineers of the Navy Department were always conscious of the danger of hidden charges of high explosives which might become operative and disastrous when the machinery was put to a test. Instances of artful pipe plugging, of concealing steel nuts and bolts in delicate cylinders, of depositing ground glass in oil pipes and bearings, of cunningly changing indicators, of filling fire extinguishers with gasoline and similar means of spoliation, were common enough to induce the engineers to make a rule calling for thorough overhauling. On each ship there was no boiler that was not threaded through every pipe for evidence of plugging, no mechanism of any sort that was not completely dismantled, inspected, and reassembled before it was finally passed as safe.

Record of Damage Found on One Ship

A memorandum written in German was picked up on one of the ships which gave a complete record of the destruction on that ship. Investigation revealed that the list, which had evidently been left through an oversight, was correct in every detail. The following is a translation of excerpts from this memorandum:

"Starboard and port high pressure cylinder with valve chest: Upper exhaust outlet flange broken off (can not be repaired)."

"Starboard and port second intermediate pressure valve chest: Steam inlet flange broken off (can not be repaired)."

"First intermediate pressure starboard: Exhaust pipe of exhaust line to second intermediate pressure flange broken off (can not be repaired)."

"Starboard and port low pressure exhaust pipe damaged (can not be repaired)."

The parenthetical optimism of the German who was so confident of the thoroughness of his mutilation is now the source of much glee among naval engineers, inasmuch as every one of the supposedly irreparable parts was in fact speedily repaired and those engines are to-day as powerful and serviceable as when they left the hands of their makers.

The method of patching and welding broken marine engines had never before been practised, although the art has been known in the railroad industry for 15 years. Three methods of patching were used; electric welding, oxy-acetylene welding, and ordinary mechanical patching, the latter often later being welded. Following the repairs tests of the machinery were first made at the docks, where the ships were lashed firmly to the piers while the propellers were driven at low speed; and later each ship was taken to sea for vigorous trial tests. The patches and welds were reported as having given complete satisfaction.

When the Leviathan, formerly the Vaterland and the largest ship afloat was put into commission by the United States Government and sent to sea for a trial run, her commander, a young American naval officer, was ordered to "exert every pound of pressure that she possesses, for if there is any fault we want to know it now." The Leviathan stood the test. She was one of the ships least mutilated, due to the fact that she was in bad repair and it was believed that she would not be fit to put to sea for many months. The navy engineers found it necessary to overhaul and partially redesign and reconstruct many important parts of the engines.

Ships Now in United States Navy

Every one of these ships was found to be either deliberately damaged or rendered useless through ravages of neglect before they fell into the hands of the United States Government.

The most serious typical damage was done by breaking cylinders, valve chests, circulating pumps, steam and exhaust nozzles on main engines, and by dry firing boilers and thus melting the tubes and distorting the furnaces, in at least one instance probably using thermit to make the destruction complete.

There were many instances of minor and easily detectable destruction, such as cutting piston and connecting rods and stays with hack saws, smashing engine-room telegraph systems, and the removal and destruction of parts which the Germans evidently believed could not be replaced. The most insidious sabotage was that which was concealed. In plugging a steam pipe the method was to disjoint the pipe and insert a solid piece of brass which would be sawed off flush with the joint. The pipe would then be reconnected, showing no evidence of having been tampered with.

Fire Extinguishers Filled With Gasoline

Indicators were astutely reversed in

many instances. Numerous fire extinguishers were found to be filled with kerosene and gasoline. Piles of shavings and refuse were strewn about where fires might be started, open cans of kerosene being found in several of these incendiary traps. There had evidently been a plan to burn the ships under certain conditions and it is believed that the German crews were seized and interned somewhat in advance of their expectations.

Case of Vaterland Distinctive

The case of the Vaterland was quite different from that of any other ship. Engineers of the Navy Department who examined the big liner declared that inferior engineering had been practised in her construction. She has four turbine engines ahead and four astern on four shafts. All of the head engines were found in good condition and all of the astern engines were found damaged.

The major portion of the damage was credited more to faulty operation than to malicious intent. Cracks were found in the casing of the starboard high-pressure backing turbine of such size as to make it certain that the engine had not been used on the vessel's last run. Certain documentary evidence found on the ship corroborated this belief. It also indicated that the Vaterland on her last trip had made less than 20 knots.

There was just enough evidence of mutilation to warrant full investigation and the vast mass of machinery, electric apparatus, and piping in the Vaterland was patiently and doggedly examined before she was sent to sea. Original defects in her engine equipment were corrected, she was overhauled and in many respects refitted, and on the whole she was declared a better ship when she entered the service of the United States than when she took her maiden voyage.

SELLING AND BURNING FUEL

By J. H. R.

FEW problems at the present time are more pressing or more difficult of solution than that of the economic utilization of fuel for industrial and domestic purposes. That the question is of vital significance has been amply demonstrated during the past few weeks by the drastic measures taken by the government fuel controllers, for the utmost conservation of coal in every line of manufacture. In an effort to comply with current regulations and assist in relieving a situation that was rapidly developing into the famine stage, users of fuel were both anxious and willing to co-operate to the fullest extent for a reasonable solution. The essential need of maintaining production was however a feature that invariably prevented a plant from curtailing on the consumption of fuel, for operating the equipment at maximum capacity.

An interesting experience in connection with coal conservation was related to the writer a short time ago, where an institution with a large power plant was induced by the official salesman of a gas concern to use coke for firing the boilers. The engineer of the plant was not consulted regarding the new developments, as the agreement to "give the coke a trial" was made in the office. The salesman for the gas company interviewed the manager respecting the adoption of coke for the aforementioned purpose. Owing to the poor quality of the coal they had been getting and the convincing persuasion of the salesman, respecting the high efficiency of coke as a heat producing medium, the manager finally decided to give the coke a trial, and placed an order for several tons for immediate delivery.

When the engineer was advised that a quantity of coke would be delivered the following day, the jig was up. The manager was informed right off the bat that it was utterly impossible to burn coke on the particular style of mechanical grate installed in the boilers. Nothing would do however but that the engineer should make ready to receive and store the supply of coming coke. He nevertheless refused to have anything to do with the "test" and suggested that the gas people supply the fireman for the demonstration, as he would be very willing to learn anything new regarding the firing of a boiler on any class of fuel. So it happened that the next day saw a number of carts discharge their load into the waiting bunkers, and with the arrival of the "demonstrator" the test was commenced. Previous to becoming an interesting onlooker, the engineer went the rounds of the different departments and advised them to be prepared for an early shut down. The manager and salesman stood quietly by as the coke specialists loaded the hopper with the recent arrival, no particular attention being paid to the size of the lumps that were thrown in. The travelling grates continued their regular course, automatically carrying the three inch layer of slack coal from the hopper to the fire chamber. The time soon arrived however, when the last of the slack coal reached the bottom of the hopper and in a very brief space of time the pressure gauge, which had been registering 100 lbs. per sq. in., gradually began to fall, so that in a few minutes the hand was pointing to 50, with the foremen of the machine departments inquiring as to the failure of the power.

As invariably happens, the practical man was at once approached for advice, when it was discovered that the coke had failed to find its way through the three inch opening, and the back half of the grate was bare of fuel, the cold air rushing through and cooling off the boiler shell. The coke was emptied from the hopper and spread on the concrete floor—all over the boiler room—and hammers were brought into play to reduce the lumps to a size that would pass through the openings of the mechanical stoker. In the meantime the bed of the fire was put in order and a fresh supply of slack placed in the hopper. When all was again ready, the coke demonstrator—still optimistic—took the leading role, and his assistants filled up the hopper with a supply of small coke. However, the result was little better than the preceding one; for while the coke passed through the opening and followed the bituminous and hard coal slack along the grates, it failed to ignite when reaching the fire chamber, and as soon as the air struck the thin open layer of coke, the rush of cold air prevented the back creeping of the fire that is necessary in the successful operation of this particular type of mechanical stoker. It was a very disappointed but wiser salesman that ordered the coke back to the bunkers and its subsequent removal next day.

Electricity and Hydraulics

SOME CONSIDERATIONS ON TRANSMISSION LINE CONDUCTORS

ALTHOUGH copper wire has been most commonly use for transmitting electric power on long distance transmission lines, with aluminum as an alternative choice, economic considerations have suggested the use of steel as a possible substitute. Its high tensile strength and elasticity would seem to render it eminently suitable for withstanding the heavy strains and the continual expansion and contraction to which conductors on long spans are subject and moreover permit of longer spans between towers with less sag and shorter towers than is possible in construction employing either copper or aluminum conductors.

But offsetting these advantages to be gained were the relatively more important disadvantages of low electrical conductivity and reactance of steel. In other words, for the same resistance loss in the line, the area of the steel conductors, if used, would have to be much greater than that of the equivalent copper conductors. Consequently the increased weight of metal might entail a higher initial expenditure for conductors than would be the case were pure copper used.

Skin Effect

Also the magnetic quality of iron or steel is responsible for what is known as skin effect where the current is confined to the outer circumference of the wire instead of being equally distributed over the cross section of the wire. The higher density of current thus occuring at the outer skin or surface causes heating which in turn reduces the conductivity still further. The same effect is present in non-magnetic conductors but not to such an extent as in iron or steel. But the principal factor precluding the extended use of steel for high tension transmission is the deterioration which it undergoes in service of this nature

A new type of conductor has been developed employing steel in combination with either copper or aluminum and it is quite possible that it will be used to some extent in future transmission line construction.

The Copper-Clad Conductor

In order to secure a conductor having the high tensile strength of steel and at the same time retain the high conductivity feature of copper, a compromise has been effected by manufacturing a copper-clad cable. It comprises a core of steel wire surrounded by an annular outer jacket of copper. The area of the copper is such that it will successfully carry the total current of the conductor without overheating, so that the magnetic action of the core which tends to force the current to the outer layers of the wire does not act detrimentally in this case.

The process of forming this copper to the steel is accomplished by driving a copper jacket over the steel billet while it is still in the wire bar stage and the subsequent rolling treatment serves to effectively weld the copper to the steel, virtually forming an alloy of the two metals at their junction. This method of manufacture requires that the percentage of steel to the total area of the conductor shall be large so that compared with a copper conductor of the same conductivity, it will necessarily be larger and more expensive due to the cost of steel and the extra operations involved in manufacture. The same objection of high reactance holds here as with the steel wire and, all things considered, the copper-clad cable will not supplant its prototype except in construction where long spans are imperative in which case the lesser number of towers required and the closer spacing distance allowable, since the sag is a minimum, will tend to simplify and cut down the cost of the system, and in proportion to the saving effected in this way will the objections to its use previously mentioned be minimized.

There are two grades of copper-clad steel commercially produced, the 30 per cent. and 40 per cent. depending on its conductivity relative to an annealed copper conductor of the same size. The 40 per cent. grade is usually specified for electrical work because it has a lower resistance and reactance than the 30 per cent. grade.

Aluminum-Steel Conductors

The success attained by the process for copper-clad wire led to trying aluminum in the same way but initial results were not satisfactory owing to the disparity in the melting points of the two metals. Further investigation produced a solution of the difficulty which proved even simpler than the first method. The individual aluminum wires were laid around a steel wire core in an ordinary stranding machine, the steel being double galvanized to prevent any electrolytic action between the dissimilar metals. Aluminum and zinc have about the same electro positive qualities. The stranding scheme carried out, ordinarily, makes a seven strand cable, the middle strand of steel and the outer six of aluminum. Sometimes the steel strand will consist of seven small steel wires having the same total area as would the single steel wire.

The Hemp Core Cable

Another type of composite conductor which has been the object of considerable interest and experiment, is the hemp core copper strand cable. It represents the substitution of a strand of hemp for the centre wire in a seven strand copper cable, thus leaving only six effective current carrying conductors. The physical qualities of the hemp are such as to prevent its very extended use. It lacks elasticity chiefly in respect to contracting the same amount it has elongated. The result, eventually, is a distorted cable and in time a seriously deteriorated hemp core. Such a cable would be 16 per cent. greater in cross section than the equivalent seven strand copper and the increased diameter reduces corona loss while new but the deterioration of the hemp will operate to cause increased corona. An improvement on the hemp cable is the practice of using an annealed medium drawn copper wire in place of the hemp core. Its elongating properties are such that the strain it at all times taken

STEAM FOR HEATING PRODUCED FROM ELECTRIC CURRENT*

By F. Haehn.

THE Swiss Society of Steam Boiler Owners recently conducted an interesting test for ascertaining the commercial possibilities of generating steam for heating purposes by electricity. The method investigated was to heat the water under pressure and, as required, allow it to expand to a lower pressure and so generate steam.

A small model tubular boiler 24 in. in diameter and 50 in. long containing thirty-eight 1¼-in. steel tubes was used for the test. Glass-insulated microhm heating coils having a resistance of 1.1 ohms were inserted in 34 of the tubes and so connected that the latter were divided into three groups of 18, 9 and 7 respectively, any of which could be cut out of service. Direct current at 225 volts obtained from a hydro-electric plant on the premises was applied.

The following table gives the results of two tests:

	Test No. 1	Test No. 2
Duration, hours	7.6	7.0
D.C. voltage	225.8	225.6
Average amperes	142.4	148.8
Aver. pressure, lb. per sq. in. abs.	25.0	23.4

*Translated from Schweizerische Bauzeitung.

Average kilowatts	32.2	33.6
Aver. temperature, deg. F	51.8	50.0
Total heat in one pound of steam, B.t.u.	1,160.0	1,163.4
Total evaporation, lb. per hour	85.5	89.7
Evaporation in pounds per square foot of heating surface at minimum demand	2.7	2.42
Evaporation in pounds per square foot of heating surface at maximum demand	2.85	2.68
Evaporation in pounds per square foot of heating surface at aver. demand	2.76	2.62
Total pounds steam generated per kw.-hr.	2.65	2.67
Theoretical heat in B.t.u. per kw.-hr.	3,415.0	3,415.0
Actual heat obtained in B.t.u. per kw.-hr.	3,074.0	3,106.3
Efficiency, per cent.	90.0	90.9

The efficiency of 90 per cent. might have been improved by better lagging, as most of the losses were due to radiation.

It is interesting to note that the evaporation per square foot of heating surface was greatest at minimum demand, owing to the better heat transfer to the water when the latter was not filled with steam bubbles. For practical purposes it is fair to assume a mean evaporation of 2.46 lb. per sq. ft. of heating surface.

The first requisite for steam generation by electricity is a cheap source of power. In order that such a system may compete with a coal-fired plant, with coal selling at $8.75 per ton in Switzerland and an average evaporation of 7 to 8 lb., the author computes that the cost of current cannot exceed 0.16c per kilowatt-hour.

Such low-cost current is rarely obtainable. However, cases may arise where an otherwise partly idle hydro-electric plant can be used to furnish the necessary current on nights, Sundays and holidays. If, then, sufficient heat can be stored in the water to furnish steam by regeneration for the entire week, the practical application of this method takes on an entirely different aspect.

The author derives a number of equations for computing the heating surface and the storage space required for furnishing the maximum amount of steam for heating purposes at a reduced pressure of 22 lb. absolute, with an available power supply of 883 kw. for 12 hours.

Given a feed temperature of 59 deg. F., the total steam obtained at a mean pressure of 99 lb. is shown to be 2,244 lb., which would require about 80 sq. ft. of heating surface. The total amount of water necessary amounts to 20,661 lb. and would require a storage space, making due allowance for extra steam space of some 400 cubic feet.

Placing the radiation losses at 6 per cent., the total amount of steam reduces to 2,109 pounds.

With an evaporation of 7.5 lb. and coal at $8.75 per ton, this represents an equivalent fuel cost of $1.23 per day, or $369 per year of 300 working days, an amount which the author believes sufficient to cover the interest and depreciation of the simple equipment required.

The system offers the advantage of high efficiency in transforming the surplus electrical energy into heat with only light storage losses and to give up this heat at any rate desired while requiring only nominal attention. It may also become the means for improving the load factor of the plant by cutting in the heating coils as the load decreases.

WATERS AND WATER-POWERS

THE ninth annual report of the commission of conservation contains extended references by the chairman, Sir Clifford Sifton, to numerous phases of conservation throughout 1917. Speaking of electric power plants he states that the preliminary survey of the water-powers of Canada is now practically completed. During the past year special efforts have been made to secure detailed information with regard to electric power plants and systems throughout the Dominion.

Power Progress in Ontario

The development of hydro-electric power in Canada, and especially in the provinces of Ontario and Quebec, during the last ten years has been almost incredible. At the beginning of the work of the Ontario Hydro-Electric Power Commission, the late premier, Sir James Whitney, stated that the Commission would not require so much as 10,000 h.p. At this moment, the immediate requirements of the Hydro-Electric Power Commission in Ontario may be conservatively stated at 296,000 h.p., upon which demand there is a present shortage of about 70,000 h.p. A conservative estimate of the amount of power actually in use in the city of Montreal and its environs is 225,000 h.p. The position with respect to the province of Ontario, and especially with regard to Niagara Falls, is one which should be considered with great care. At the present time, the Hydro-Electric Power Commission is about 70,000 h.p. short, and it is not too much to say that this shortage will rapidly increase. I understand that Sir Henry Drayton has reported to the Federal Government that it is not practicable to withdraw this 70,000 h.p., which is presently in demand, from the United States to which it is now being exported, for the reason that the power is necessary for the use of plants which are producing essential war material for Great Britain and her allies. The position is, therefore, that, whereas, 12 or 15 years ago, it was not thought that the Hydro-Electric Power Commission could make use of 10,000 h.p., and, accordingly permits to export were more or less freely given, there is now, in round figures, an immediate demand for 300,000 h.p., and the demand cannot be satisfied.

St. Lawrence Power Situation

A situation analagous to that in which Niagara power stood fifteen years ago now exists on the St. Lawrence river. A very large capacity for the development of power exists upon the St. Lawrence. There is a considerable development in the neighborhood of Montreal, but the greater portion of the power still remains undeveloped. Attempts are constantly being made to fataly complicate the position with respect to St. Lawrence power by securing the privilege of private development, which will be followed by contracts for the exportation of the power developed. I understand that the Cedars Rapids company exports something like 60,000 h.p. per annum. An attempt was made some years ago to secure the privilege of developing the Long Sault power, the purpose being to export the greater portion of the power in the interest of a manufacturing corporation on the United States side of the line. This project was defeated, largely through our efforts. A similar project is now being promoted, and wew are resisting it with all our energy and we trust with fair prospects of success. It is almost incredible that any responsible man should be so short-sighted as to favor this project in the face of the experience which we are now undergoing at Niagara.

International Development Proposed

Within a very few years, there will be a demand for every horse-power that can be developed on the St. Lawrence river to which Canada is entitled for use upon the Canadian side. The situation with regard to Niagara will undoubtedly be duplicated, and if we are foolish enough to allow vested interests to be created upon the other side of the line, we shall inevitably find ourselves handicapped and embarrassed as we now are with respect to Niagara power. For myself, I have no doubt at all what ought to be done with respect to the great powers dormant in the St. Lawrence river. The United States Government is not interested in the corporations that are endeavoring to get possession of the St. Lawrence powers from the other side. Neither is the Canadian Government interested in the fortunes of the gentlemen who are promoting their projects on the Canadian side. They are very few in number, and their interests are confined entirely to themselves. What the United States Government and the Canadian Government alike are interested in is that there should be a fair division of this power, that it should be developed in such a way that the neighboring and tributary population should have the use of it upon fair terms. A thorough study of the whole question inevitably leads to the conclusion that there is only one sound and satisfactory method of developing these powers, and that is by an international commission, under which the greatest and the best use of the powers will be made, the most economical development will be effected, a just and equitable division of the power will take place and the governments concerned will be able to administer the power as the Hydro-Electric Commission administers the power of Niagara for the benefit of the people who are directly concerned in its use.

Powdered rosin and gypsum are the chief ingredients of a fusible insulating and filling material for electrical purposes which has been patented.

Steam and Its Generation

MODERN PRACTICE IN APPLYING GAS FIRING TO STEAM BOILERS*—I.

By T. M. Hunter, M.A., B.Sc.

IN studying the subject of gas-firing boilers, the author has come across no books dealing with both the theoretical and the practical side of the question. This is all the more surprising, as gas-fired boilers have now been in use for a very great number of years. There are many excellent books on boiler firing, but these do not generally touch the special problems which arise when seeking for the maximum efficiency and output of a gas-fired boiler. It is little wonder that engineers in charge of gas-fired boiler plants make so little progress in the direction of improving the results at their boilers. Most of them know that these results are wretched, and most of them have attempted, with little success in most cases, to make improvements.

The theory of the combustion of gas is simple; but to know what is the best combustion arrangement for any particular set of conditions, and, when this is fitted, to be able to run it so as to get the best results, are matters requiring much study and experience. Most engineers have not access to the formulæ and tables which would enable them easily to test the results they are getting at their gas-fired boilers, so the author has included in this paper a number of tables which he hopes may be of service.

The author does not claim originality for much of this paper. It is made up from information and experience gleaned here and there in years of study of the subject. If some of the matters seem very elementary, experts will forgive it for the sake of those not so well up in the subject.

First Use of Gas

Gas as a boiler fuel was first used in connection with blast furnaces some where about the middle of last century. Boiler firing was the obvious use to which to put the gas recovered as a by-product in the manufacture of iron. Gaseous fuel is apparently the ideal fuel for boiler firing. It requires no stoking and no cleaning of fires. A whole battery of boilers can be attended to by one man, and a constant load is maintained independent of the efforts of manual labor. The main reason why blast furnace gas has not been used with greater success is that it carries huge quantities of dust. This is deposited in the boiler flues, resulting in a constant decrease of the evaporation and requiring to be cleaned out every few weeks. Under these circumstances the possibilities of the fuel were not realized. About 25 years ago gas-cleaning plants were introduced, which provided cleaned gas and did away with this disadvantage.

The introduction of regenerative coke-oven plants next provided quantities of gas, which was also used for boiler firing. On account of the higher calorific value of coke-oven gas very much smaller quantities had to be handled in order to obtain the same results from boilers. It was found that this gas could be brought into contact with the walls of boiler flues without being extinguished, and so brick-lined combustion chambers were not generally used for its combustion. It was, however, found that even with this richer gas the efficiency of gas-fired boilers was still very low.

The theory gained ground that gaseous fuel was unsuitable for boiler firing, and that it was impossible with it to obtain anything like the efficiency or the evaporation obtainable in the same boiler by coal firing. This theory is still held by many engineers. It is the more surprising that this theory should have taken such a strong hold, as at the same time the most perfect combustion arrangements were invented for small quantities of gas. We generally connect these improvements with the name of Bunsen, and the Bunsen principle is at the back of most of the work that has been done on large volumes of gas, as well as on small volumes.

About 20 years ago the Mond by-product producer, followed by other producers, provided another source of gas in large quantities, and in some cases this gas was used for boiler firing. The author thinks that in no case yet has gas firing of boilers with by-product producer gas been made a commercial success, as it has been found that steam could be raised more cheaply from the coal direct, even after allowing for all the income from the sale of by-products. He does not wish to be misunderstood in saying this, as he firmly believes that there are modern producer and boiler plants even now on the market which can make the gasification and gas-firing proposition a commercial success under suitable conditions.

Engine Developments

Many engineers came to the conclusion that they would have to give up boiler firing with by-product producer gas as commercially impracticable, and they turned their eyes to gas engines to utilize the gas economically. Gas-cleaning plants had made the use of producer and blast-furnace gas possible in gas engines. It was soon seen that gas engines would produce 1 h.p. for at most 10,000 therms in the gas. This was at a time when it was assumed that some 20 lb. of steam per horse-power were required in a good steam engine. As this represented over 19,000 therms in the steam, and as this steam had to be generated in gas-fired boilers at not more than 50 to 60 per cent. efficiency, the gas engine apparently was to be the engine of the future. Probably this would have been found true but for the adoption of steam turbines, which have reduced the steam per horse-power to about 10 lb. It was also found that the power per horse-power taken by gas engines increased rapidly as the load was reduced, whereas in turbines this was not the case. Turbines could be overloaded without danger, they could be made in units of very much larger size than the largest gas engines, and they were found, unlike gas engines, to be more economical in the larger sizes. In initial cost the turbine plant was cheaper, and in reliability and in cost of maintenance the gas engine was a very long way behind. It became evident that if gas-fired boilers could raise the steam at 75 per cent. efficiency the results from a modern turbine set would be as good as those from a gas-engine set, while as regards reliability and the skilled attendance required the steam turbine was unquestionably first.

There is no doubt that gas-fired boilers have now a greater future than ever. Probably the time is not so far distant when our present method of burning coal, together with its valuable by-products, will be considered obsolete, and possibly even illegal. It will then be replaced by some type of by-product producer or coal distillation plant yielding gas, and this gas will without doubt be largely used for boiler-firing purposes.

Calorific Value of Gas

The calorific value of a gas is expressed as the number of therms contained in 1 cubic foot, or the number of calories contained in 1 cubic metre of the gas. It is the custom to quote the calorific value of a gas at normal temperature and pressure. In this country we quote the number of therms in 1 cubic foot at 60° F. and 30 in. mercury column. On the continent normal conditions are 0° C. and 760 mm. mercury.

The calorific value of a gas is found

*A paper presented before the Institution of Electrical Engineers.

by burning the gas in a calorimeter and measuring directly the heat produced. This method reduces all the products of combustion to the temperature of the atmosphere, and thus condenses the water vapor arising from the combustion of H^2 and hydrogen compounds. The value thus obtained is called the "gross calorific value" of the gas.

In almost every case where gas is burned for practical purposes the water vapor arising from the combustion escapes to the chimney as a vapor and is not condensed. It has, therefore, become the custom to treat the latent heat lost through the non-condensation of this water vapor, not as a charge against the boiler, but as a charge against the gas itself. The "net calorific value" of a gas—which is the value generally quoted—is the gross calorific value, less the latent heat of the water vapor of combustion.

If in any special case the products of combustion are cooled down so far that some of this water vapor does condense, a calorific value more nearly approaching the gross calorific value would have to be used, otherwise the results shown would be quite deceptive.

To calculate the calorific value from the analysis of a gas we multiply the volume of each constituent by the calorific value of that constituent and add together the results. The following table shows the calorific values of the common constituents of gas; and an example is added to show the method of using the table:

	Gross calorific Values		Net Calorific Values	
	Therms per cub. ft	Calories per cub. metre	Therms per cub. ft.	Calories per cub. metre
Carbon monoxide, CO.....	344	3,062	344	3,062
Hydrogen, H_2	342	3,042	293.5	2,613
Methane, CH_4	1,063	9,460	966	8,598
Ethylene, C_2H_4	1,724	15,300	1,627	14,480
Hydrogen sulphide, H_2S	659	5,860	619	5,513

Calorific Value of a Coke-oven Gas.

Analysis, per cent.		Net Calorific Value.
H_2	49.1	$0.491 \times 2{,}613 = 1{,}282$
CH_4	32.6	$0.326 \times 8{,}598 = 2{,}800$
C_2H_4	3.1	$0.031 \times 14{,}480 = 449$
CO	8.1	$0.081 \times 3{,}062 = 248$
N_2	6.6	
O_2	0.5	4,779 calories per cub. metre
	100.0	=537 therms per cub. ft.

The question of gross or net calorific value of the gas often leads to misunderstandings. It is evident that when gas is produced from coal in a coke oven or producer plant the steam actually raised in boilers, per ton of coal put into the plant, is not affected whether we talk about the gas by its higher or lower calorific value. It is only when we investigate the efficiency of the various parts of the plant that this question arises. The maker of the producer naturally wishes to use the higher calorific value of the gas so as to show a high producer efficiency, while the makers of the boiler and combustion arrangements wish to use the lower value because the difference between the two values is a loss which is not recoverable in the boiler. It is advisable in all contracts that it should be clearly specified which value of the gas is to be used, so as to avoid any possibility of friction.

Below are indicated the losses arising from the latent heat of this water vapor in the case of several typical gases, and suggestions are made as to the possibility of reducing these losses. In all the calculations given in this paper the net calorific value of the gas is the value used.

Value of Gas

Among the by-products recovered from the distillation of coal, the manufacture of iron, the destructive distillation of coal and other processes, gas takes a very important place, and a much more important one than is generally realized by those who receive huge volumes of gas as a necessary and certainly welcome result of processes which primarily were not started for the purpose of manufacturing gas. It is common knowledge that in many modern manufacturing processes a very large proportion of the profits must of necessity be derived from by-products; it will, therefore, be worth while to consider more closely the value of gas when used under boilers.

Coke-oven Gas.—Let us assume a coke-oven plant of 50 by-product ovens which deals on an average with 100,000 tons of coal per year and yields 6,000 cub. ft. of surplus gas of 450 therms per cub. ft. per ton of coal. Let us further assume that this gas is burned with the assistance of a suitable combustion arrangement, giving an efficiency of 80 per cent. It would then be possible to generate 220,000,000 lb. of steam from and at 212° F., which corresponds to 96,500 tons of steam per year.

If the value of a ton of steam to a colliery is taken at 30c, the value of the surplus gas will be just over $30,000, and each 1 per cent. efficiency lost or gained will make a difference of $300. In other words, if the 100,000 tons of coal should produce 70,000 tons of coke, the total value of the gas will be nearly 42c per ton of coke.

Blast-furnace Gas.—The question of gas efficiency for the ironworks owner is a still more important one. It can be taken for granted that of the heat generated in a blast furnace 50 per cent. is consumed by the process of making iron, and that the other 50 per cent. is recovered in the blast-furnace gas.

If we assume one ton of coke to be used per ton of iron and the value of blast furnace coke to be $4.32 per ton, $2.16 per ton of iron is represented by the calorific value of the gas. Part of this gas must be used for heating the blast, but by far the greater part is available for the gas-fired boilers, gas engines, and the like.

If the stoves consume 30 per cent. of the surplus gas, and if 10 per cent. be allowed for losses through bell lowering, 60 per cent. is available for boiler firing, so that this portion of the gas with which we are chiefly concerned represents a value of nearly $1.32 per ton of coke.

Let us assume that a ton of coke is equivalent to 27,800,000 therms; then 13,900,000 therms per ton of coke will be available in the gas, and if 60 per cent. of that is surplus for boilers and gas engines, 8,340,000 therms can be burned under boilers.

If we again assume a boiler efficiency of 80 per cent., 8,340,000 therms would give 3.13 tons of steam from and at 100° C. per ton of coke. If the value of steam at iron-works is 48c per ton, which corresponds to a coal price of $2.88 and an evaporation of 6 lb. of steam per lb. of coal, we obtain $1.50 worth of steam per ton of coke.

In order to realize the economical importance of the whole question, let us assume the case of an ironworks with four furnaces using on an average 3,000 tons of coke per week. The value of the coke for boiler-firing purposes is in their case $243,750 per year, and each 1 per cent difference in efficiency means a difference of no less than $2,435. It is hardly credible, yet true, that scarcely any ironworks obtains a boiler efficiency of more than 50 per cent., and that many get an efficiency much lower than this, so we see that small ironworks as described above are losing 30 per cent. of $243,750, or $73,050 worth of steam a year, which could easily be recovered. The question of gas economy is thus seen to play a most important part in the financial prospects of ironworks.

Returning again to the case of the ironworks described above, the loss per ton of coke is at least 46c when assuming an efficiency of 50 per cent. As efficiencies are frequently as low as 40 per cent. the actual losses sustained are often over 62c per ton of coke.

The manufacture of pig iron in Great Britain was some 10,000,000 tons a year before the war, so that if the average loss is only 48c per ton, the formidable sum of $5,000,000 a year is sent up the stacks of the ironworks of Great Britain.

Producer gas.—Very few people at present use producer gas for boiler firing. On the other hand, at many works there are considerable amounts of waste products, like belt pickings, coke breeze, shale, etc., which are very rich in combustible matters and yet unsuitable for boiler-firing purposes. Any proposition

would be welcome which would render it possible to turn these waste products to profitable account without endangering the stability of the steam supply.

The fallacy of a producer gas proposal for boiler firing without absolute security of the results obtained in the boilers is evident if the following figures are taken into consideration. A modern producer will yield nearly 75 per cent. of the heat contained in the fuel as heat in the gas, and with the old combustion arrangements hitherto in vogue no higher efficiency than 50 per cent. can be counted on, so that only 37½ per cent. of the heat in the fuel appears as heat in the steam.

If we take a fuel containing 12,000 therms per lb., the total steam raised in a gas-fired boiler per lb. of fuel in the producer would not exceed 4½ lb. from and at 212° F. Then, again, 1½ lb. of this had to be returned to the producer in the blast, so that the net evaporation for outside purposes was only 3 lb. per lb. of fuel. Under ordinary circumstances the same fuels fired into boilers would have given 7 or 8 lb. of steam per lb. of fuel. With modern combustion arrangements an efficiency of 50 per cent. with producer gas can be raised to 75 per cent., so that fuel of 12,000 therms will give 7 lb. of steam per lb. of fuel; and as with the latest by-product recovery producers the steam necessary for producing by-products has been reduced to the amount necessary to drive the blowers, etc., the actual yield would be over 6½ lb. of steam per lb. of fuel. The result in steam for outside purposes is not materially worse than if the fuel had been burnt in the boilers, and the by-products are available to provide for depreciation, interest, and profit.

Suitability of Gas for Boiler Firing

Coke-oven gas.—Coke-oven gas gives comparatively higher efficiencies than the two other kinds of gas in gas-fired boilers owing to the greater ease with which it can be burned. The nature of the gas, however, renders it difficult to make burners which will deal with large quantities of gas. The comparatively narrow flues of Lancashire boilers offer so much resistance to a speedy expansion of the burning gas that unless we use forced draught the evaporation from coke-oven gas in Lancashire boilers is confined to 5,000 to 6,000 lb. per hour. If, therefore, new boilers are contemplated it will always be advisable, provided that the quality of the water permits it, to choose water-tube boilers. Coke-oven gas is particularly suitable for firing water-tube boilers, and with suitable combustion arrangements evaporations of 5½ lb. per sq. ft. of heating surface can easily be obtained at the highest efficiency.

Blast furnaces and producer gas.—Blast furnace and producer gas though of comparatively low calorific value, provided that they are clean and supplied under suitable pressure, will give good results, both in Lancashire boilers and in water-tube boilers. With Lancashire boilers evaporations of over 8,000 lb. per hour can be obtained, and with water-tube boilers 5 to 5½ lb. per sq. ft. of heating surface.

Blast-furnace gas we have to accept as it comes from the furnaces. It is so important that the iron made should be exactly what is required, that the kind of gas produced is never likely to be a matter of much concern to the blast furnace manager. We must accept the fact that occasionally the gas is hardly combustible at all, and we must devise means to deal with this condition.

The matter is different in dealing with producer gas. Gas is here a valuable product, though only the second product in point of value. The manager of the producer has it in his power to give us a gas which is much more or much less suitable for boiler firing. We naturally wish the richest possible gas, as it is the easiest gas to burn. At one large Mond plant the gas was found to be just under 100 therms per cub. ft., while at many plants the gas is over 150 therms per cub. ft.

WELDING AND CUTTING PROCESSES IN BOILER WORK*

By A. F. Dyer.**

At the present price of material, scarcity of labor and difficulty of obtaining steel and iron, welding and cutting by both the above processes has proved a great boon and an almost indispensable factor in railroad repair shops.

Seven years ago we employed one man as an acetylene welder and owing to failures through his lack of experience the process was nearly condemned, but as we gathered experience both gas and electric welding developed, so that now instead of one man we employ eighteen and have often to work them overtime.

Acetylene Systems

The low pressure acetylene gas system is used and the whole shops are piped for the acetylene; every other repair pit has a drop connection; in roundhouses we use dissolved acetylene in cylinders, which saves the expenses of a generator and piping where the process is only in use occasionally.

There is a great difference in opinion as to the relative merits of high or positive pressure and low pressure gas, the manufacturers of pressure outfits contending that you save oxygen by using their type of generators and claim that you can not get so near to a netural flame with the low pressure gas as you can with the high; the makers of the low pressure outfits claim that by the use of an injector embodied in the torch or welding head a neutral flame can easily be obtained; we find we can obtain a flame as nearly neutral as can be obtained with the outfit we use, although with pressure gas you can obtain a much larger flame for the same size head than with the low pressure. The principal factor, however, that made us decide on the low pressure outfit was the fact that our main supply pipes are carried overhead throughout the shops, and as nearly all, if not all, oil, steam and water pipes are overhead, we had to consider a very well known motto, viz., "Safety First," for if a man was working overhead and by mistake broke a joint of the gas pipe his torch or candle might cause an explosion, which might wreck the shop. I may say that, though we have been using the acetylene gas for eight years, we have never had an explosion of any sort yet. Our low pressure generator went through a big fire two years ago, and we were enabled to repair it and use it for several weeks till we received our new outfit.

Electric Outfits

There are many kinds of electric welding outfits on the market, and, of course, each one is claimed to be the best by its respective makers; each has its advantages, and the old prejudice very often exists among operators that the machine they are using and are familiar with is the best, and they will stick to that opinion until they become accustomed to the new machine. A new equipment using alternating currents instead of the direct current is now being put on the market, and only weighs 150 lbs., and gives from 20 to 200 amperes, and is about 50 per cent. cheaper than any D.C. machine on the market.

The electric welding outfit consists of two generators, each operating four welding circuits; the shops are wired, and at convenient places connection boxes are placed and only need a lead and ground wire connected to them and the work on which the welder is engaged.

The outfit used has panel controls, which allows each man to control his amperes independent of the other welders.

The processes have proved themselves fitly to be ranked amongst the greatest time and labor savers, and also we may safely say money-savers, introduced for a long period. For instance, in the not very distant past, a locomotive with a broken frame was due for a period of several days in the shops before they could strip down one side and remove the frame to the smith's shop, weld it, and perhaps have it machined and then replaced; now we drop the pair of wheels which may cover the break, cut out the crack with the cutting torch to the shape of a double V at an angle of 90°, clean off the oxide caused by cutting and weld up with the metal electrode, using soft steel or Swedish iron, a frame 4 in. x 5 in. being cut and welded in under 14 hours, and it can be done in less time by having two operators on the frame at once, but the men do not like facing each other's arcs, as when they are changing their filling rods their eyes get sore.

Frames, when worn by brake gear and stays, are built up and worn holes are plugged and welded instead of reaming them out to a larger size and thereby weakening the frame. In rebuilding and superheating engines the same boilers are seldom used on their original frames, and in very few cases do the various holes in angle irons, furnace bearers,

*Read before the Canadian Railway Club, Montreal, Dec. 11, 1917.

**General Foreman, Welding Dept., Grand Trunk Railway, Montreal.

etc., come into alignment with frames or boilers; these holes are welded up and redrilled.

The present price of tool steel demands that none shall be wasted; therefore, we use it down to the last inch by welding it to tire steel. Twist drills, taps and reamers when broken near the socket end are welded and put into use again; for this purpose we use either the electrode or gas, but in both cases we use vanadium steel filling rods, as we find this gives the best results. Spokes of driving wheels are welded and flat spots on tires have been successfully welded up when it was necessary to do so.

Up to now we have not had much success on cast iron with the iron electrode although with the carbon you can make a fair job, but the gas is unquestionably the best for any of this material. We have successfully welded with the gas, steam shovel engine frames, slides and cylinders by welding in patches of cast iron where worn or broken. When our contract for shells was completed and the lathes that were used for this purpose were being overhauled, it was found that most of the V slide beds were worn down by the tool carriers; these were built up with the gas, which saved machining these beds down in many cases ⅜ in.

Boiler Work

In regard to boiler work, most of the welding is done with the iron electrode, using a mild steel or Swedish iron as a filler; it is found that the electric process localizes the heat more so than the gas, though it is the writer's humble opinion that the gas makes a closer and neater weld, as all welds made by the electrode are more or less porous unless hammered up. It pays better whenever possible to do so to put quarter or half sides in order to get out of the fire line in preference to putting in a patch, for, as a rule, however well the patch is welded it generally gives out in from twelve to eighteen months' service, and the same applies to cracks, whereas the half or quarter side should last as long as the firebox.

When a nest of small cracks is found round the staybolts the bolts are removed and the holes countersunk and welded up. This method has been found to be very successful. Corner patches are welded in by running the patch into the tube or back sheets, as the case may be, at the same time removing the flanges. If it is decided to do away with a number of tubes, plugs are welded in the holes, first countersinking the holes and having the plugs punched by a countersunk die which gives the proper bevel for welding.

A great deal of trouble was experienced when welding in the superheater flues and tubes when this was first started, but after a little experience much better success was arrived at. Some operators prefer the tubes belled and others prefer them beaded; some prefer the water in the boiler and others do not.

The operators I am connected with like the belled methods best and with the water in the boiler. This keeps the tube sheet from heating, especially round the smaller tubes. Tubes are set in with copper ferrules set back 1/32 in. and the flues are belled out 3/16 in. to 7/32 in. and the small tubes 3/16 in. The sheet is roughened all round the tubes and flues, and the oil is then burnt off with the oxy-acetylene flame and tubes and flues welded in with electrode, using ⅛ in. mild steel or Swedish iron; the latter is preferred if caulking is needed.

Output Performance

A sample of an average day's work is as follows for a gang of 12 men:

14 rivet holes in smokebox and 4 peg holes in foundation ring.

10 tube holes in upper portion of firebox tube sheet.

2 air pipes which were worn through.

In the tool room:

1 ratchet for jack (2 teeth replaced).

1 gear spindle built up.

1 chuck screw key end built up.

1 boring shaft built up from 2½ in. to 2⅞ in.

2 tool holders rebuilt.

1 air hammer handle repaired.

6 teeth in lathe gear built in.

1 cone, small end filled up solid.

2 1¼-in. holes in top rail of frame filled up.

4 cracks 18 in. long in right side sheet welded.

14 bottom tube holes welded up.

2 washout plug holes built up for retapping in round head.

Cut out frame for welding and started welding same.

Welded bushes in pony truck stays.

Cut out 3 sets of boiler tubes.

Cut out 1 set of superheater flues.

Build up caulking edge of fire hole.

Heated corners of tube sheet for closing.

Welded broken superheater damper bracket.

Built up reversing lever where worn.

Built up 2 side rods where worn.

Cut out 48 flexible staybolts in firebox.

Welded 2 cracks in throat sheet.

Air Brake Department:

1 broken flange of air brake cylinder.

In addition to this list two men are engaged continuously on cutting around the shops.

For cutting steel and wrought iron the oxy-acetylene process has practically no competitor, it being impossible with the carbon point to cut as fast or as fine and neatly as the gas torch, although for scrapping fireboxes and frames, the carbon point is cheaper if time is no object and labor cheap.

The foregoing examples only enumerate a very small fraction of the uses to which the two methods of welding and cutting are being put to in locomotive repairing and machine shops, and fresh uses are being found for it every day.

Both Processes Valuable

No roundhouse should be without an oxy-acetylene outfit, both for repair work and as a part of the wrecking outfit; many days are lost by engines being tied up through parts having to be sent to the nearest big shops for repair, which could be repaired on the spot with a welding and cutting outfit. All large roundhouses should have both processes, as they would pay for themselves over and over again.

In concluding, I would state that though there are many different opinions as to which is the best process, no shop is complete unless it has both equipments, although the gas has really the widest range, but, on the other hand, a heavy piece of steel or iron needs no preheating with the electrode, but welding can be commenced as soon as your arc is drawn; 95 per cent. of the failures which occur, instead of being laid on the process, should be placed on the shoulders of the operators.

Welding should not be treated as a side line of the machinists' or boilermakers' business, but should be treated as a trade in itself, as it really is, for it needs the entire concentration of a man's mind, careful study, plenty of practice and a conscientious man to make a welder.

Wherever possible a separate building or suitable space should be provided for bench work, and should be equipped with a suitable furnace for heating and annealing castings, and also have plenty of floor room to allow of charcoal fires being built for preheating cast iron jobs for welding.

STRIVING AFTER NATURE?

CONSIDERABLE notoriety has been achieved during recent months by an individual rejoicing in the name of Giradossian, who has influenced certain members of the United States Congress sufficiently to bring before the House a scheme which he wishes to have tested by the Government. The entire proceedings have been so irregular and spectacular that more than ordinary interest has been aroused in engineering circles. Our contemporary "Power" treated the matter editorially in a recent issue, and its comments are very much to the point. Under the caption "Power from the Air," it says:

It is recorded that the Lords of the British Admiralty rejected the propeller when it was proposed by Ericsson, and Dr. Lardner demonstrated that a steam-propelled vessel could never cross the Atlantic. In the absence of a demonstration the injector might well have been regarded as a mechanical absurdity, and a proposition to converse across miles of space, without even a wire connection, would have sounded insane a half-century ago.

The open-minded attitude induced by the contemplation of such instances need not, however, lead one to take seriously a proposition to make ten pounds of sugar out of nine pounds of cane, or to take out of a train of mechanism more energy than is put into it.

Garabed T. K. Giradossian, an Armenian mechanic, claims to have invented a "free energy generator." This, he says, is not a perpetual motion, but makes available a free source of energy, by which vessels may be propelled to any distance without stopping to coal up, airplanes may fly around the world and

carry thousands of pounds, torpedoes may be projected at great speed, and the speed of steam engines doubled (although it is not apparent what we should want of the poor old steam engine any more).

We have a great admiration for Garabed T. K. Giradossian, not as an inventor, for our office is the depository of countless schemes for the multiplying of power and evading the law of the conservation of energy, but as a promoter. In "Power" for July 31 was told how he had appeared before the House Committee on Patents, which issued twenty-five pages of printed report about his invention and various subjects more or less touching on and appertaining thereto. The committee has now reported a bill which went through both Houses of Congress with a whoop, providing that the device shall be tested by a board of five scientists to be selected by Mr. Giradossian and approved by the Secretary of the Interior.

Every once in a while somebody discovers that water is a combination of oxygen and hydrogen, and declares that all that a vessel has to do to secure an unlimited supply of fuel is to decompose some of the water upon which it is floating and burn the hydrogen that is produced with the oxygen from which it has been separated. The trouble is that the water is the product of a previous combustion of hydrogen—a union of hydrogen and oxygen—and that it takes just as much energy to separate them as they generate in coming together, just as it takes as much energy to hoist a weight as it will give back in falling.

Is there any reason to hope that Mr. Giradossian's project has any firmer foundation?

It cannot be said that Mr. Giradossian's dream is impossible of realization. The process is going on continually before our eyes. Carbon, in its various forms of coal, wood, charcoal, oil and other fuels, is burned by combination with oxygen, the product of the complete combustion being carbonic-acid gas. To decompose a pound of this gas would require as much energy as would lift a ton weight over one hundred and fifty feet, but here comes in one of the most wonderful, beautiful and mysterious of nature's processes. It is a peculiar property of vegetation that under the influence of sunlight it can overcome the attraction which exists between the atoms of carbon and oxygen, appropriating the carbon to its own use, building it into its structure, and letting the oxygen go free into the atmosphere.

To separate these two elements in our laboratories, we are obliged to resort to the most powerful chemical agents and to conduct the process in vessels composed of the most refractory materials, under all the violent manifestations of light and heat; and we then succeed in liberating the carbon only by shutting up the oxygen in a still stronger prison. But under the quiet influence of the sunbeam in that most delicate of all structures, a vegetable cell, the chains which unite together the two elements fall off, and while the solid carbon is retained to build up the organic structure, the oxygen the atmosphere. To separate a pound of carbon from the oxygen with which it unites in burning would require the expenditure of an amount of energy which would raise the weight of a ton to the height of over a mile, and yet in the economy of nature this process is constantly going on, not with the noisy demonstration of prodigious effort, but quietly, in the delicate structure of a green leaf waving in the sunshine.

Has the Armenian mechanic discovered the secret of the vegetable cell?

VARIABLE SPEED TRANSMISSION DEVICES

IT is curious to note how after a century or more of intense mechanical development some of our most widely used machines and mechanical devices are of a type that appears to outrage every mechanical principle. The picking motion of the loom is one such device, the combination of motor cycles and side car is another, the sliding gear variable speed device for power driving road vehicles and other machines is a third. A study of some of these apparently barbaric suvivals leads to the conclusion that their practical advantages outweigh fundamentally their technical deficiences, and suggests that they are not likely to be superseded by more "correct" devices that will better satisfy the mechanical sense. They may be all wrong, but they give more for a dollar than any alternative arrangement. But in other cases they appear to owe their continued existence to the fact that being early established as a standard device, a hundred times more effort has been given to their improvements than to the development of any radically different and, perhaps better method, so that the competition continues to be between an actual much improved bad thing and a prospective ill-developed good thing.

Whether the sliding change speed gear now employed on the overwhelming majority of road motors belongs to the first or second of these arrangement classes it is as yet too early to say, but the arrangement is too crude to go for a long time unchallenged. R. E. Phillips in a paper on variable speed gears, read some time ago before the Institute of Mechanical Engineers, admits that although from an engineer's point of view it is theoretically an embodiment of everything that is wrong, it has been developed by the perfection to which its design has been brought, by the high standard of workmanship employed in its manufacture and by the use of the highest grade of materials into a completely satisfactory piece of mechanism. In practice it has proved to be "not so bad as it looks," and it has managed to hold its own for nearly 20 years against many other gears which theoretically should give better results. This condition of things has attributed, however, partly to the factor above mentioned, that nothing like the same attention has been devoted to other transmission devices as to this, and partly to the fact that the motors now used are of such a gen is allowed to return to its home in high horse power that at least 75 per cent. of the running is now done on the direct drive.

The amount of effort that has been given to the improvement of the side meshing type of change-speed gear is evidenced by the number of varieties that have been evolved. These have been catalogued by M. Rutishauser, an eminent French engineer, into no fewer than 9 main divisions and 20 sub-divisions. The most frequent aim of the inventor has been to prevent undue wear and tear on the teeth of the wheels due to the clash engagement, and the problem has been tackled in many ways. The side mesher action can, of course, be altogether at a price. All that is necessary is to keep the several trains of gears constantly in mesh, and bring into action the particular train required by means of some of some form of clutch. This method, though theoretically attractive, has in practice three weighty drawbacks; it increases the length and weight of the gear box; it adds greatly to the complexity and cost and it means that all the wheels are running all the time. A happy compromise is that in which the sliding wheels are mounted loosely on their shafts, and are brought into mesh with the respective corresponding wheels of their trains before they became coupled to the shaft on which they are mounted.

SUPPLIES OF GASOLINE

IN 1915, Canada consumed over 43,000,000 gallons of gasoline. Of this amount about 5 per cent. was produced from Canadian crude, while the remainder was either imported direct or produced from imported crude. This fact shows the dependence of Canada upon supplies of gasoline and petroleum from United States and strengthens the argument used in a previous issue wherein it was stated that 20 per cent. of the gasoline used in Canada was produced from Canadian crude oil.,

TENDERS WANTED

TENDER forms and specifications have been received from D. H. Ross, Canadian Trade Commissioner, Melbourne, for equipment required by the Department of the Navy, Melbourne, and the Postmaster General's Department, Brisbane, Queensland. These tender forms are open to the inspection of Canadian manufacturers at the Department of Trade and Commerce, Ottawa. (Refer File No. 1729 O.) Particulars of the requirements are briefly outlined thus: The tender addressed to the Director of Navy Contracts, Navy Office, Melbourne, is as follows:—Supply and delivery of one motor driven hydraulic pump for Garden Island, Sydney, N.S.W. Date of closing April 5. Tenders addressed to the Deputy Postmaster General, Brisbane, Queensland, are as follows:—Schedule, No. 432. Fifteen miles, 550 yards silk and cotton insulated switchboard cable, as specified; 990 yards paper-insulated, rubber covered cable, as specified; 8,880 yards lead-covered, paper-insulated telegraph cable, as specified. Date closing Feb. 27.

THE ETERNAL QUESTION

WITHOUT artificial heat, man, as he is to-day, could not exist in the greater part of the temperate zones of the earth—that is those portions having moderate extremes of heat and cold. Without power, man, in the present condition of the world's population, could not maintain civilization in its present high degree of advancement. Light could be dispensed with to a great extent if man cared to subdue his desires for many artificial features of our existence.

Heat and power are just as essential to the continuity of life on this planet as a supply of fresh air, food and water is.

The sources of these two vital elements become increasingly valuable as time passes. Coal is simply a substance which gives forth heat under specific conditions. Its extent is limited within approximately known amounts, and, when exhausted, can not be replaced. It is not a source of heat in the same sense that a spring is the source of a river.

A real source of power is that medium or relation of natural forces whose operation is continuous in periodical regularity and will continue so, short of some cataclysmic occurrence which would completely alter climatic conditions on the earth.

The symbol of man's future existence and his natural heritage is the waterfall. Simple streams of water drawn toward the earth by gravity are, in the final analysis, mankind's salvation. Unknown discoveries may yet make available other methods of utilizing the energy of the sun for the benefit of man, but the continual, vast and unchangeable process of evaporation and condensation will for centuries to come be the source of energy wherewith man can maintain his present conditions of life.

An economic feature of hydro-electric power generation as opposed to steam electric is the absence of complexity in the apparatus. The advent of the steam turbine removed much of the complication found in reciprocating engines but the questions of fuel supply, handling and combustion remain with their respective losses due to carelessness of operation, types of equipment and inherent and unavoidable features of existing conditions. In the case of hydraulic power generation the percentage of efficiency is largely, though not all, fixed by the excellence of design in general plant layout and the maintenance of such at a high level involves less manual labor and consumption of stores as well as the absence of heavy losses which can be sustained through careless boiler house operation and lack of upkeep in steam engine efficiency.

BUYING COAL ON A HEAT BASIS

THE purchase of coal on a basis of contained heat units appeals to the engineer who is accustomed to judging the majority of materials on an efficiency basis. As a standard of value it is the only correct method of classifying fuels apart from types such as hard, soft, etc., each of which has individual characteristics rendering it more or less suited for specific purposes.

It is stated that since 1906 the $8,000,000 worth of fuel purchased annually by the United States Government has been bought on B.t.u. and chemical bases, and it is suggested that our own government might well adopt such a plan in buying over $1,000,000 worth of coal yearly. Where large amounts such as these are dealt with, the system is equitable as the producer must have a production large enough to allow inequalities of cost, etc., to balance up.

As the better grades get exhausted, they cost more to mine, and relatively may give the producer a smaller profit per ton than a lower grade easily mined coal which can be sold on the open market at ruling prices irrespective of its efficiency as a heat producer.

The root of ultimate trouble is the fact that coal is not a manufactured product and must be accepted as Nature made it. Perhaps when national fuel control is an accomplished fact, the manipulation of coal for by-products will enable a standard fuel to be made available which will possess a nearly uniform heat content and avoid many inconsistencies which would arise if the heat basis were adopted on a wide scale at present.

Association and Personal

M. J. Beatty, of Beatty Bros., Fergus, Ont., has been elected a director of the company. He succeeds the late G. P. Scholfield.

W. H. A. Fraser, of Fraser & Co., and director of the Hull Power Co., died at his home in Ottawa on Feb. 4. Mr. Fraser was born at Westmeath, Ont., in 1863.

Edward G. Mack, managing director of the Crouse-Hinds Co. of Canada, Ltd., Toronto, has been elected to the executive council of the Toronto Board of Trade for the ensuing year.

Flight Lieut. Ralph Gordon Hall, of the Royal Flying Corps, was accidentally killed whilst flying in Birmingham, England, on Jan. 22. His father is Thomas Hall, president of the Hall Engineering Works, Montreal.

William Allan Foley, who for seven years was superintendent for Goldie & McCulloch Co., Galt, Ont., died in that city on Jan. 27, in his 75th year. The deceased had lived in Galt over fifty years.

Lloyd Harris, president of the Russell Motor Co., who has been associated with the British War Mission in Washington for several months, has been appointed chairman of the Canadian War Mission in that city.

W. F. Tye, of Montreal, president of the Sterling Coal Co., Toronto, and former chief engineer of the C.P.R., has been named a member of the Commission of conservation to succeed the late Sir Sanford Fleming.

Sir John Wolfe, Barry, widely known engineer, officer of numerous engineering and allied societies, member of the army railway council and consulting engineer to many railway and public works corporations, died in London on Jan. 23. He was born in 1836.

F. F. Backus, general manager of the Toronto, Hamilton & Buffalo Railway, with headquarters at Hamilton, has been appointed railway traffic expert in charge of traffic at the Canadian terminals on the Niagara frontier. The position has been created by the Canadian Railway War Board for the purpose of supervising and expediting freight traffic from the United States.

William A. Noble, chief engineer at the Normal School, Toronto, for the past twelve years, died suddenly on Monday morning at the home of his brother, Trustee Dr. John Noble, 219 Carlton Street. A few days ago he was seized with la grippe, which resulted in complications. The late Mr. Noble, who was born in Peel County 57 years ago, had spent the last twenty years in Toronto. He was a member of the Masonic order and a member of L. O. L. No. 140. The body will be interred at Mono Centre.

C. C. Curtiss, successor to E. L. Milliken as manager of the Cape Breton Electric Co., has arrived in Sydney, N.S., and will immediately take up his new duties. Mr. Milliken leaves early next week for Houghton, Mich., where he will manage another branch of the company's system. Mr. Curtiss was recently stationed in Texas where he was engaged in a similar capacity with Stone and Webster to that which he will occupy here.

PERMISSIBLE TEMPERATURE OF COAL PILES

THE permissible temperature which a coal pile can be allowed to attain, according to the "Travelers Standard," is 150 degs. F., this having been adopted in a number of cases as a standard and no serious trouble experienced so far as is known.

It is conceivable, however, that there might be an appreciable diminution in the calorific value of the coal if it were subjected to prolonged heating at a temperature approaching 150°, even though actual ignition did not take place. It is therefore recommended that a maximum temperature of 130 degs. F. be allowed, which will probably be safe under almost all conditions.

Under certain conditions a considerable rise in temperature may take place within a short time. A rise of this kind may stop before it reaches the danger point, but, on the other hand, it may continue and result in spontaneous ignition; therefore, if such a rise is observed, steps should be taken immediately to check it. A recent case is illustrative of the conditions that may cause such a sudden rise in temperature. At a certain plant a steam pipe passed through a coal pile, but it was not expected that this pipe would cause any trouble because it was heavily insulated with a covering of 85 per cent. magnesia. Nevertheless, a rapid rise in the temperature of the coal pile was noted (the coal at this particular plant being under close observation for the purpose of detecting possible heating), and thereupon the steam was shut off before the danger point was reached.

OPERATOR ORGANIZATIONS

British Columbia Association of Stationary Engineers, Vancouver.—Subordinate Lodges at Vancouver, Victoria, New Westminster, Cumberland, Merritt, and Fernie.

North-West Association of Stationary Engineers, Edmonton, Alta.

Manitoba Association of Stationary Engineers, Winnipeg.

Canadian Association of Stationary Engineers, Hamilton, Ont.—Subordinate Lodges at Montreal, Toronto, Hamilton, Ottawa, Brantford, Guelph, Kitchener, Chatham, Ont.; St. John, N.B.; Owen Sound, London, Stratford, Belleville, Kingston, Sudbury, St. Thomas, North Bay, Port Arthur, Sarnia, and Windsor, Ont. The executive officers of the C.A.S.E. Grand Lodge are as follows:—

Past President—W. G. Forbes, Montreal, Que.
President—R. F. Gofton, Kitchener, Ont.
Vice-President—Wm. Cooke, Belleville, Ont.
Treasurer.—A. W. Heath, Hamilton, Ont.
Conductor—S. Balmfirth, Toronto, Ont.
Doorkeeper—George Moll, London, Ont.
Secretary.—John H. Hale, Hamilton, Ont.

RELATION BETWEEN INDOOR AND OUTDOOR TEMPERATURE

INVESTIGATIONS involving the making of records of indoor and outdoor temperatures at regular intervals, and also the fluctuations of the temperature of the hot water used in the heating systems showed that for each degree drop in temperature outside an increase of 2° F. in the water temperature was sufficient to keep up the room temperatures. It was also shown that the lowest water temperature recorded 100° F., and the highest 160°, proved that the boiler capacity and the amount of radiation were sufficient.

Largest Locomotive in the World.—The greatest steam locomotive in the world has been put into service by the Baldwin Locomotive Works, Philadelphia, Pa. It is so gigantic that its boilers had to be made flexible at three different joints so that the locomotive could turn around a curve. It is more than 100 feet long and weighs some 450 tons. Twenty-four driving wheels, each standing as high as an average sized man, afford its traction. The driving wheels are distributed along the length of the locomotive in sets of four pairs, the wheels of each set being coupled together and driven by two giant steam cylinders. Under full steam the locomotive can exert an 83-ton pull on cars behind it, which means that it can easily haul a freight train two miles long and 23,000 tons in weight over an ordinarily good roadbed at an average of fourteen miles an hour, and possibly more. Bad roads will retard it only slightly.

The Operators' Point of View

DOES A PISTON STOP AT REVERSAL?

I WAS quite interested in the articles by R. W. Millar and W. F. Schaphorst on the subject of whether or not a piston stops on reversal. As Mr. Millar's query brought only one reply, and as no one undertook to diagram the problem, I decided to try to put another spoke in the wheel.

Personally I never had any doubt but that the piston stopped on reversal. With Mr. Schaphorst I thought that if it did not stop how could it ever start moving in an opposite direction and all in the same straight line?. The only question in my mind was: Did it actually stand at rest for even an infinitesimal length of time? As for giving a verbal solution of the problem I do not think that any one answer would satisfy everybody. From time to time we hear quite a bit about the personal element or the human factor as a variable and uncertain, but very important, item in economics, production, etc., and I am of the opinion that this element is the chief factor in the solution of this problem. By way of explaining my meaning I will cite the following two incidents.

Once when several of us were together, A made the assertion that a perfect circle had never been made. Most of us thought that circles perfect enough for all practical purposes could readily be drawn or laid out, but we finally consented that an "absolutely" perfect circle could not be made. We were expecting to be joined by a young Englishman whom A knew to have been acquainted with the noted Druids' Circle. This Englishman soon arrived, and a few minutes later A had directed the conversation in such a way as to lead the Englishman to mention the said Druids' Circle, and he incidently remarked on the stones that were placed so as to form a perfect circle. To this remark A replied: "We had just agreed a few minutes ago that a perfect circle was an impossibility." Of course some of us felt that some one had been duped, and I still believe that A had deliberately planned the catch.

In another instance a young man went to a manufacturer and ordered a perfect straight-edge three feet long to be made of glass. The manufacturer said "We cannot make it perfect, we may get it within a fraction of a light wave, but we cannot make it perfect. The young man asked what the price would probably be and (if I remember right), was told it would probably be about forty thousand dollars. Later it became understood that the straight-edge was not wanted for optical purposes, and that for the purpose for which it was wanted a variation of one thirty-second of an inch from perfect would not materially affect its usefulness. Under these conditions the cost of the straight-edge was but a small fraction of one per cent of the first named price.

The point which I wish to emphasize is that what to one man is true, straight, or perfect, may to another be very imperfect.

Aside from this, there is a more or less true saying that "You cannot convince a man until he convinces himself," and another that "A man convinced against his will is of the same opinion still." Therefore I would advocate that each sufficiently interested operator try this thing out for himself by the making and studying of diagrams such as I am about to describe. The study of small diagrams does not bring out the actual movements nearly so clearly as will large size diagrams carefully made.

One of Mr. Millar's stipulations is the assumption that there is no lost motion in the parts. Now, supposing that we have an engine with a two-foot stroke and a connecting rod five feet long from center to center of its bearings, it is obvious that if there is no lost motion the center of the crank pin will travel in a circle having a radius of one foot, the diameter of the circle being two feet. It is also obvious that if there is no lost motion, and if the piston remains absolutely without movement, the centre of the crank end bearing of the connecting rod can only move in the arc of a circle having a five foot radius or describing a portion of a circle, which if completed would be ten feet in diameter. Now if each interested operator will, with reliable beam compasses, using a fine-pointed pencil, draw upon a sheet of plain paper firmly held on a good drawing board or other plain surface a few curves having a five-foot radius and inside of each of these, draw a curve having a one-foot radius, he will, by noting to what extent they coincide as shown in Fig. 1, be able to study for himself the amount of movement of the piston while the crank is travelling past or near the crank end dead center. Fig. 2 shows a few curves having a five-foot radius and outside of each of these draw a curve of one-foot radius (the backs of the curves toward each other). One is thus able in the same way to study the movement of the piston while the crank is travelling past or near the head end dead center. These latter curves fall apart much quicker than do the former ones which shows that if the piston actually came to rest at each end of the stroke the period of rest would be shorter on the head end of the stroke than on the crank end of the stroke. It also shows that the speed at which the piston travels when just approaching or receding from the dead center at the head end of the stroke is greater than the speed at which it travels when just approaching or receding from the crank end dead center.

FIG. 1.

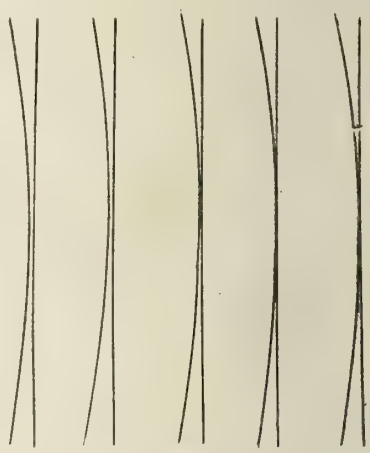

FIG. 2.

By drawing a number of curves as recommended above, one can have some

pairs made so that the two lines merge into one another at their centers, while in other pairs one can leave a small space between them which I think gives a better chance to judge of the actual amount of piston movement represented by their differences.

In the head end curves the back-to-back position will, by optical illusion, give the wider curves the appearance of having a straight portion near their centers, but by holding the paper nearly edgewise to the eye this illusion disappears and it is also then easy to see that no part of either curve forms a straight line, neither do they travel exactly parallel to each other for any distance. They merely, in a varying degree, approach to and recede from each other and can really coincide at one point only, thus indicating that the piston comes to a stop at this point but starts back again without resting. Mr. Millar would perhaps prefer not to use the term point, since according to geometry a point has no dimensions. If so, we can choose another though less convenient term approved of and used in geometry. We can speak of a degree or a fraction thereof.

We all know that there are three hundred and sixty degrees in every circle or circumference.

In the case of our two-foot circle the circumference in inches is $24 \times 3.1416 = 75.398$ ins., and one degree equals $75.398 \div 360 = .2094$ in., or just over one-fifth of an inch. There are sixty minutes in a degree and sixty seconds in a minute, so we can get down to pretty fine measurements by counting in seconds of a degree or fractions of one of the seconds, or we can speak of thousandths or other decimal parts of a degree if we prefer. It is here that the personal element or human factor feature comes into play, and I am of the opinion that the man who considers as perfect almost any circle carefully drawn with reliable compasses, or who would consider as perfect the cheaper one of those two glass straight-edges above mentioned, would also be satisfied that the piston remained at rest, while the crank was passing through an arc of one or two degrees at the crank end dead center.

On the other hand the type of man who considered that a perfect circle had never been drawn, or who required precision in a straight-edge even to a fraction of a light wave, or who delighted in extremes of micrometer precision in measurements would unhesitatingly assert that the motion of the piston was continuous, though not of uniform velocity. I also believe that so long as men differ thus widely in their ideas as to what constitutes exactness, just so long will there be a difference of opinion on this question, but I may be misjudging my fellows. At any rate this method of constructing diagrams affords to each an easy means of deciding the problem to his own satisfaction, for, given good instruments, he can bring into play all the scientific accuracy and all the hard practical common sense he considers it necessary to apply. There is also this added simplicity as compared with some other engine problems—there is no necessity for taking connecting-rod angularity into consideration. The angularity of the beam of the compasses used in describing the wider arcs sufficiently duplicates that of the connecting rod.

Perhaps after making and examining a few of the curves the following solution of the question may appeal to some. Improvise a definition something like this: The dead-center is an imaginary point, having no dimensions. Then state that the piston stops at the time when the crank is passing the dead-center. Finally claim that since the said dead-center has no dimensions, the piston does not stop long enough to have any period of rest between strokes.

Up to now I have been assuming that there is no lost motion, but of course this condition cannot be completely obtained in practice. We must have sufficient play to avoid undue friction with its attendant overheating and loss of available power for useful work. Given an engine having light reciprocating parts and a high degree of compression, the lost motion present may not really affect tse relative motion of the crank and piston to each other while passing the center since the compression forces the piston, when nearing the end of the stroke, to take up all the lost motion available. In the case of other engines, and in the case of a belted pump, for instance, the effects of lost motion are more noticeable. I believe, though, that it is needless to further dilate on this latter phase of the subject.

I would like to add, that where there is at hand a compass with a capacity of six or seven feet radius I would recommend that curves of over five feet radius be used in the diagrams. My own would not extend to six feet, therefore I used the five.

A PISTON DOES STOP AT REVERSAL

By W. Fletcher Shepherd

IN his revival of this time-honored controversy in the December 6th issue Mr. R. Hamilton attempts by an ingenious argument based on Euclid's definition of a line to prove that a piston—theoretically—does not stop at reversal. Euclid's definition of a line as having length but neither breadth nor thickness is now, however, regarded as insufficient for modern analytical mathematics. According to the modern mathematical conception a line is the trace or path of a point moving in space or in a plane and its breadth and thickness are infinitely small as compared with its length.

That this conception is based on sound reasoning a moment's consideration will show. A point on a body moving along any path or line must pass through a multitude of points so that the line itself is composed of an infinite succession of points. If then a point has no dimensions at all no progress could be made along the line since if nothing be added to nothing the sum is nothing no matter how often the process be repeated.

Now it appears to the writer that the piston problem can be very simply settled by a close observation of the pin joining the connecting rod to the crank. The path of the crank pin center is a circle and in a well balanced engine the crank pin moves around its entire circular path with practically no lost motion. Its reciprocating motion, however, in the direction parallel to the piston axis varies in acceleration and speed from a maximum at the middle of the piston stroke to zero at each end of the piston stroke. We also observe that at each end of the piston stroke the crank pin centre crosses the piston axis at right angles and can therefore at that instant have absolutely no movement in either direction along that axis. The breadth of that axis may be infinitely small and the time consumed in crossing it infinitely short but the essential fact remains that there is an instant when the crank pin has absolutely no movement in either direction along that axis and this is true irrespective of the speed of the engine.

Now since the crank pin is linked to the piston the latter also at that instant can have absolutely no movement in either direction along its axis and since these are the only directions in which it can move the piston must therefore for that instant be at rest.

SECURING GAS-TIGHT PISTON RINGS

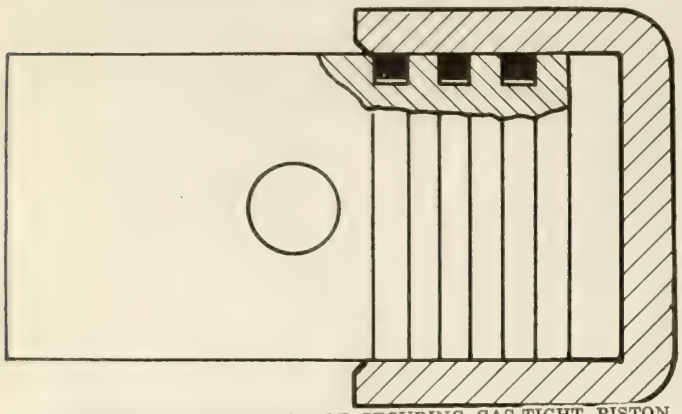
By A. L. Loy.

TROUBLE is often experienced with the leakage of compression past the piston rings in gasoline engines. This is more often true with the cheaper makes of farm engines, on many of which the standard of workmanship is low. This leakage of compression quite naturally cuts down the power which the engine will develop as well as resulting in an increased fuel consumption. Needless to say it is extremely annoying at all times.

When the piston is being pushed back into the cylinder on the compression stroke the friction between the rings and the cylinder will naturally retard their movement, and they will rest against the side of the groove toward the shaft, leaving a slight clearance on the opposite side. Now, if the side of the groove and ring as well is rough or uneven the metals will not come in contact completely around, allowing a small space through which the gases will pass. In manufacturing care is always taken to see that one side of the ring is well finished and the same is true in the piston. If these two surfaces are in contact a fairly tight joint may be obtained.

The method here described was seen by the writer in a small gas engine shop which had had trouble in securing perfect results along these lines, and it is well adapted for use in the repair shop also. A casting is bored out to just slip over the rings and piston, bevelled at the edge so the rings will enter easily. A thin mixture of emery flour and oil is

poured into the ring grooves and the casting slipped over, and, as it is pushed forward, it will carry all the rings in the same direction so they will rest against the sides of the grooves, when they may be ground to a seat the same as a valve, using a rotational movement. This method has worked out admirably, and has resulted in cutting down the rejections due to leaky rings and pistons.



ILLUSTRATING METHOD OF SECURING GAS-TIGHT PISTON RINGS.

PACKING ECONOMIES

IN the November number, J. M. talks about packing economies.

I remember a plant in which there were a great many cylinder heads to pack and as the heads had to be removed frequently, and the work was not always done carefully, the plant was a bonanza for the packing manufacturers. With a view to economy we tried asbestos yarn, but not exactly in the manner described by J. M.

We first applied shellac or varnish to the cylinder heads inside the bolt holes and then a few turns of asbestos yarn, being careful to get a turn close up to the part that projects into the cylinder in order to prevent a pocket for condensation, and having the outside turn just inside the bolt holes.

We did not wrap anything around the bolts or studs as that appears to be unnecessary. The shellac eliminated any worry as to the yarn staying in place. It stayed put.

We then painted the cylinder flange inside the studs with a mixture of plumbago and cylinder oil which enabled us to use the same joint repeatedly, saving packing and time. The pressure carried was at least 130 lbs., and asbestos is good for a considerably higher temperature than that to which it was exposed.

St. Catharines. R. McLAREN.

A WATER LEVEL ALARM

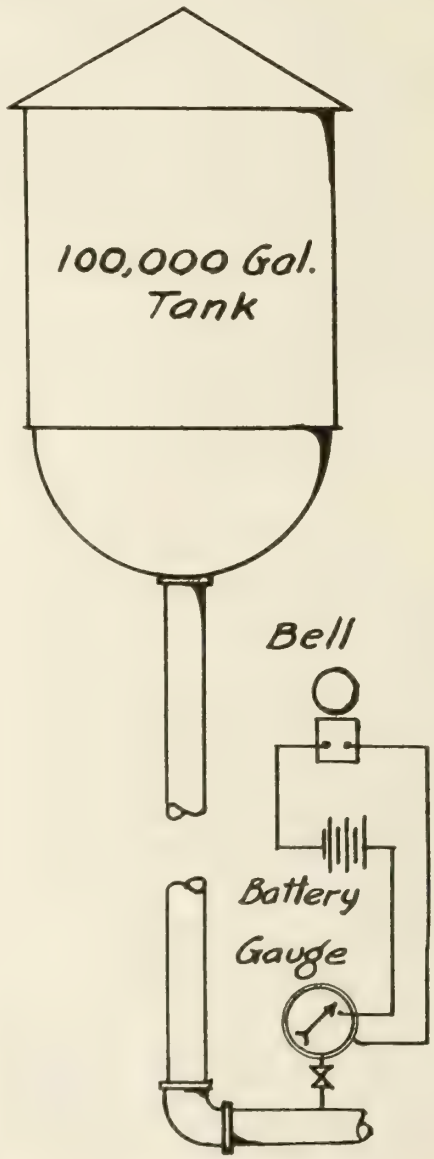
By Wm. Hall

HERE is an idea which I have tried out very successfully in connection with an overflow alarm for a water tank 175 feet high. Should this tank overflow, water would drop on a high tension line immediately below; the danger of this being apparent as the potential is 13,000 volts and the wires might easily be broken by the formation of ice.

As the pumps were in the basement an electrical alarm system was attached to the pressure gauge as shown in the accompanying illustration.

Gauge pressure corresponding to the water level in the tank is easily obtained by multiplying the height in feet by .424. This figures out at 45,-950 lbs. per square inch when the tank is full.

By the connection of an electric bell to the gauge quadrant and the arranging of same so that it rings when the pressure reaches 42 lbs. per square inch, the pump man is given due warning when the water level is about 3 feet from the top.



A WATER LEVEL ALARM.

WATER LEVEL ALARM

By James E. Noble

THE low water alarm shown by J. C. McDonnell in January POWER HOUSE reminds me of something along the same line, but simpler and more permanent in design and which obviates the disadvantage of being water soaked, even under extreme conditions, as where there is steam in the return.

Fig. 1 shows an outfit which is easily constructed and installed. A is one end of a bell and battery circuit, attached to any part of the iron tank. B is the other terminal fastened rigidly in any manner so long as it is insulated from the tank. C is a small iron counterweight and D is a copper float, these being connected by a fine wire cable E, which passes over the pulley F. This pulley is attached to the tank by the upright piece G.

When the water lowers, the weight C rises and connects with B, completing the circuit and ringing the bell. The float will not wander all over the water surface as the counter weight will keep it in its proper position at all times.

Fig. 2 shows another scheme which is very satisfactory. A 3 in. pipe is attached to the tank shown at B. A cylindrical float A has a thin wire attached to it passing through a wood or fibre guide piece C at the top of the pipe. The piece H insulates the wire from the metal bridge piece G-G. D and E are two branch wires from a lighting circuit and F is a red lamp placed in a convenient place.

When the water gets low the gap F F is closed and the red light shows.

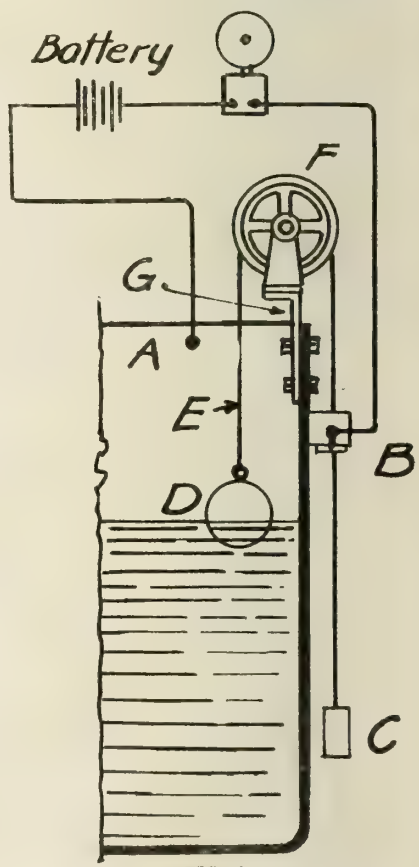


FIG. 1.

READERS' QUERIES

I HAVE a small direct current machine of about one K. W. capacity, 125 volts, and I want to use this machine for the purpose of charging 40 amp. hour. 6 volt storage batteries. Would you kindly give me a drawing showing the proper method of wiring, the position of meters, resistance, etc., and also let me know how many of the above batteries this machine would charge at one time. I can put any speed on this generator up to 1,750 r.p.m. Geo. F. Harrington.

Answer

It is assumed that the generator is shunt wound, this type in any case being the most satisfactory for the purpose and the 40 amp. hour rating of the batteries is also assumed to be at the somewhat standard rate of 5 amperes for 8 hours; 8 hours being the usual time on which discharge rate is based.

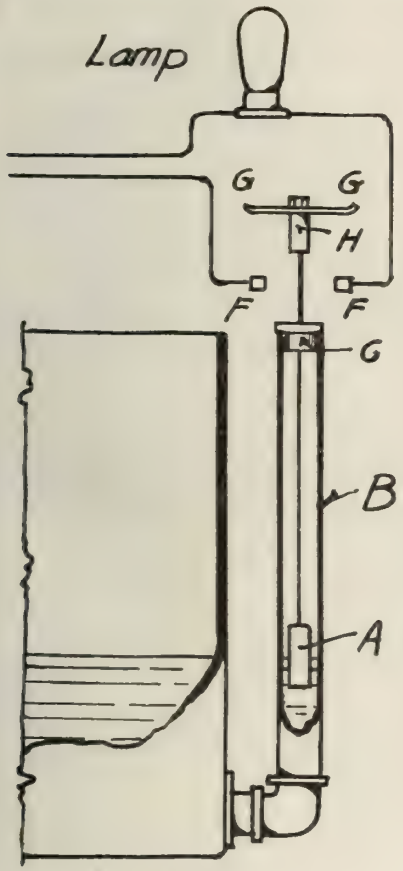

FIG. 2.

The approximate maximum charging voltage for the above batteries will be in the neighborhood of 2.5 × 3 = 7.5 volts per battery, which would give a possible number of 125 ÷ 7.5 = 16 batteries in series on one charge. Since the batteries, when on charge, will have an assumed charging current of about 5 amperes and since the generator has a capacity of 8 amps. at 125 volts it will be seen that there will be ample capacity for the purpose.

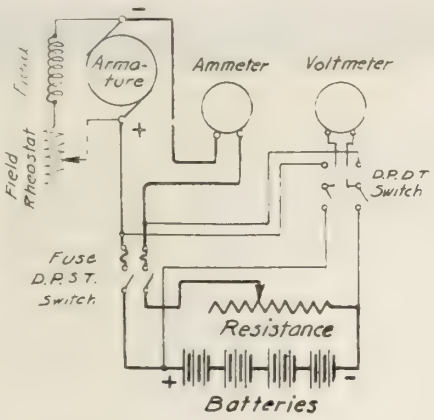
The resistance required in the rheostat in series with the cells, is given by

$$R = (E—2N) \div I.$$

Where:

I = charging current in amperes.
E = E. M. F. of generator.
R = resistance in ohms required.
N = number of cells.

Since it is supposed that it might be desired to charge one battery only at a time and since each battery will consist



of three cells, (N) will have a value of three, (I) will have a value of approximately 5 amperes and R = (125—6) ÷ 5 = 23.8 ohms. The rheostat therefore should have a continuous rated carrying capacity of at least 8 amperes, should have as a mixiumum resistance a value of 25 ohms and should have about ten to fifteen steps.

The ammeter should have a full scale reading of 10 amperes and the voltmeter should read from zero to about 150 volts.

The accompanying diagram gives connections suitable for charging any number of cells up to the maximum number allowed by the generator. It should be noted that the positive side of the generator is connected to positive side of the battery. After bringing the generator up to speed, measure the voltage of the cells and adjust the field rheostat of the generator, until the voltage of the latter is a few volts higher than that of the cells, before closing in the main switch. This precaution is of course only necessary when the number of batteries to be charged approaches the maximum number possible for the generator voltage. The resistance in the rheostat in series with the cells should be so adjusted in conjunction with that of the field rheostat as to give the proper charging current called for by the makers of the cells.

* * *

WE have a dry kiln of about 20,736 cubic feet capacity. How many lineal feet of 1 in. pipe would it require to heat the kiln up to 140 deg., using exhaust steam? Woul it be necessary to have a steam trap on this pipe, and, if so, what size? E. Towers.

Answer

THE number of lineal feet of pipe required will depend to a large extent on the shape of the dry kiln, but 6,500 lineal feet of 1¼-in. pipe, or about 8,300 lineal feet of 1-in. pipe would be about right. You would probably find the 1¼-in. pipe the more economical of the two.

The feed for the dry kiln would probably be tapped off your main exhaust line, in which case a trap would be advisable, the condensate being returned to a hot well for boiler feed if desired.

A trap capable of handling about 3,000 sq. ft. radiating surface would be right.

MACHINE OIL VS. AUTOMOBILE ENGINE OIL

By D. A. Hampson

A screw machine that had been running 1,800 R.P.M. was put on a brass job and its speed increased to 2,600 R.P.M. It gave continual trouble in the main bearings—heating up, sticking, stopping. Plenty of good "machine oil" had been used but that made no difference. When automobile engine oil was tried the the trouble stopped right away and the machine ran as well as at the lower speed.

OILING MACHINERY

INSTEAD of going over machinery with an oil can in hand it is now possible to oil it automatically. Geo M. Rogers, of Chicago, has invented an oiling apparatus which is operated by electricity and which can be put to work at any time by setting the mechanism just as one would set an alarm clock.

The oiler has a cup with an oil-feed opening in the bottom. An oilfeed pipe is connected with the cup and a plunger rod is so arranged that it gives vertical movement in the cup. A valve fitted at the lower end of the plunger fits the opening when the plunger rod is lowered. A guide pin extends downward from the valve and a gasket adapted to bear on the bottom of the cup when the plunger is lowered is arranged under the valve. The valve and plunger are operated by electricity.

If it is desired, an electric light may be included in the circuit which operates the oiler so the attendant may be able to watch the operation.

GRAPHITE REMOVES BOILER SCALE

IT IS claimed that boilers troubled with scale—especially when caused by magnesia—will not only cease to form scale, but will have gradually removed that already formed if a small amount of graphite is used with the feed water. The action on the magnesia in the water is to precipitate a mixture of magnesia and graphite in the form of a slime which may be easily washed out, while on the scale already formed the particles of graphite seem to work in between the scale and the steel, gradually loosening the scale as the treatment is kept up. In particularly bad cases the boiler should be inspected at the end of the first ten days and not less than every fifteen days thereafter for a couple of months. After this every thirty days will probably be sufficient.

Operators' Instruction Course

EDUCATION PAPER—V.

HOW many tons of work are performed by an ammonia condenser using 300 Imp. gals. of water per minute at 60° Fah., the water leaving the condenser at 90° Fah.?

Water flowing over the condenser at the above rate and under the above conditions carries $(90 - 60) \times 3{,}000 = 90{,}000$ B.t.u.'s per minute, or $90{,}000 \times 60 \times 24$ B.t.u.'s per 24 hours.

Since one ton of refrigeration necessitates the absorption of 284,400 B.t.u., the number of tons of work will be $90{,}000 \times 60 \times 24 \div 284{,}400 = 450$ tons nearly.

* * *

One hundred and sixty U. S. gals. of brine per minute are pumped through a brine cooler. The ingoing brine has a temperature of 35° Fah. and the outgoing brine 15° Fah. How many tons of work?

Taking the specific heat of brine solution as .9, the amount of heat given up by one pound of solution will be $(35 - 15) \times .9 = 18$ B.t.u. per min. The amount given up by 160 U. S. gals. will be $18 \times 160 \times 8\ 1\text{-}3 = 24{,}000$ B.t.u. per min., or $24{,}000 \times 60 \times 24$ B.t.u. per hour.

Since one ton of refrigeration necessitates the absorption of 284,400 B.t.u. the number of tons of work will be $24{,}000 \times 60 \times 24 \div 284{,}400 = 121$ tons nearly.

* * *

The temperature of liquid ammonia is 84° Fah. and the temperature of the brine in the cooler is 20° Fah. The liquid ammonia in order to evaporate must first be cooled from 84° to 80° Fah. This cooling takes place right behind the expansion valves where part of the liquid evaporates and extracts the heat from the remaining liquid. The latent heat of liquid at 82° Fah. is 502.9 B.t.u. nearly.

Assume that 100 lbs. of the ammonia has been cooled down from 84° to 80° Fah., the amount of heat absorbed by the cooling medium (evaporating ammonia) is $100 \times 1.0058 \times 4 = 402.32$ B.t.u.

This requires the evaporation of $\frac{402.32}{503.9}$ lbs. of ammonia—that is, a total of $100 + \frac{402.32}{503.9}$ lbs. of ammonia have to be passed through the system at this point to obtain 100 lbs. of the liquid ammonia. The percentage loss of liquid ammonia will be

$$\frac{402.32}{503.9} \div \left(100 + \frac{402.32}{503.9}\right) \times 100 = 0.79$$

A suction gas pipe, not insulated and passing through a room at 60° Fah., is causing a loss, as the pipe must be frosted to deliver saturated gas. How many B.t.u. are lost to condense and freeze one pound of moisture on the pipe?

To cool one pound of moisture from 60° Fah. to 32° Fah. requires approximately $60 - 32 = 28$ B.t.u.

To freeze it takes 144 B.t.u. more. Thus to place one pound of ice on the pipe will require $28 + 144 = 172$ B.t.u.

* * *

What will be the percentage of strength of a double-riveted joint of the following dimensions:—Thickness of plate, 7/16 in.; diameter of rivets, 13/16 in.; pitch of rivets, 2.708 in.?

The efficiency of a double-riveted lap joint is given by the following formulæ taken from the Ontario Steam Boiler Act:

$$Kt = (P - d) \div P$$
$$Ks = 2a \times C \div PT$$

Where $2a$ = area of two rivets in single shear.

C = a constant = Shearing strength of rivets per sq. in., divided by the tensile strength of the plate per sq. in.

C may be taken as:

.85 for iron rivets in steel plates.
.70 for steel rivets in steel plates.
.65 for iron rivets in steel plates.

Kt = efficiency of plate in joint.

Ks = efficiency of rivets in joint.

P = pitch of rivets in inches in outside row when calculating the efficiency of joints.

d = diameter of rivets after driving, equals diameter of rivet holes in joint.

T = thickness of plate in inches.

Substituting the values given in the problem or in the above formulæ, Kt is found to equal .7 and Ks is found to equal .61.

The efficiency of the joint will be governed by the lower of the above figures, and thus will be equal to 61 per cent.

* * *

A gusset stay is to support a surface 13 by 13 in.; it is ½ in. thick by 10 in. deep, and fastened to the plate with four ¾-in. bolts. What pressure will you allow on such a stay?

When gusset stays (attached to plate between two angle irons) are used their area should be 10 per cent. in excess of that required for diagonal stays, but as diagonal stays can be used in most cases where gusset stays can, they should be given the preference.

The working pressure allowed on gusset stays is calculated as follows:

$$\frac{Swt \times W \times T}{E} \times \frac{L}{H} \times .9 = B, \text{ where}$$

E = area in sq. inches of surface supported.

Swt = working tensile strength in lbs. per sq. inch.

W = width in inches of web of stay at narrowest part.

T = thickness of web in inches.

H = the length of stay.

L = the length of a line drawn at right angles from the surface to be supported to a point on this line at right angles to the end of the diagonal stay.

Substituting the values given in the above formula, and assuming that the gusset makes an angle with the shell of 30° (that is that H & L are in the ratio of 2 to 1.732, or $\frac{L}{H} = .866$), and further using for the width of the plate the net width between bolt holes, the value for B, or the working pressure, will be found to be:

$$\frac{11{,}000 \times \frac{1}{2} \times 6\frac{1}{2}}{13 \times 13} \times .866 \times .9 = 210$$

lbs. per square inch approximately.

The above shows that this gusset is amply strong in tension across the weakest part at the bolt holes, and it will be necessary to consider the value of the four ¾-in. bolts, which are assumed to be in double shear.

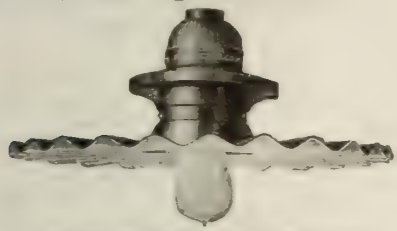
One ¾-in. bolt in double shear has a value of about 5,300 lbs., and so the total value of the four bolts will be $5{,}300 \times 4 = 21{,}200$ lbs., and the working pressure allowed from the above will be $21{,}200 \div 13^2 = 126$ lbs. per sq. in. which will govern, as it is less than the working pressure allowable for tension in the gusset plate itself.

The United States super-dread-nought Tennessee will be driven by four alternating-current motors, one to each propeller shaft, supplied by current at 3,400 volts from two 13,500 horse-power turbo-generators. The motors will be wound for both 36 poles and 24 poles, operating on the former as squirrel-cage machines and on the latter as wound-rotor machines.

Progress in New Equipment

HIGH TENSION STREET LIGHTING FIXTURES

WHEELER high tension series street lighting fixtures are designed to provide a high factor of safety with very substantial mechanical construction and convenient reflectors to properly centre the filament of the lamp so as to give the widest possible light distribution.



SHOWING COMPLETE FIXTURE

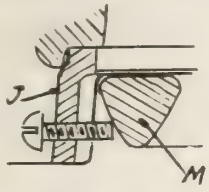
These are all built around the Wheeler high tension series porcelain receptacle head, which is a self-contained unit of high grade electrical porcelain having a spring clip series receptacle moulded in one piece with it, and so designed as to provide ample insulation with a wide margin of safety against accidental grounding on high tension circuits.

This head is supported by a cast iron canopy with three set screws in the lower edge of the skirt to firmly grip the insulator. It is threaded at the top for ¾-in. or 1¼-in. iron pipe, as may be desired, and plain or ornamental brackets of several designs are supplied, which are so constructed as to give ample support under wind stress even in exposed locations.

A cast iron skirt (J) securely bolted to the insulator has three set screws to support the different types of reflectors and globes used therewith. The reflectors

are flat and fluted to give the desired wide light distribution, and are drawn down with a deep neck to properly position the reflecting surface above the filament centre. These reflectors are attached by means of the set screws in the skirt, which pass through holes in the collar of the reflector and bear against a galvanized seating ring (M) with an inverted wedge shape cross section. The tightening of the set screws against this seating ring prevents the reflector from rattling in high winds, and thus prevents chipping of the enamel.

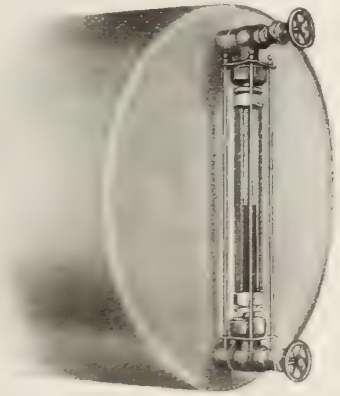
The insulator has ears on opposite sides moulded in one piece with the porcelain. These ears are pierced with holes, through which the lead wires are tied before entering the ports under-



neath the skirt of the insulator that lead to the terminals inside the head, or the wires may be brought down through the brackets directly to the terminals when the fixtures are used for concealed wiring.

SAFETY GAUGE GLASS

AN improved gauge glass is being manufactured by the Nason Manufacturing Co., 71 Fulton Street, New York, and several important advantages are apparent in its construction.



SAFETY GAUGE GLASS AND HOUSING

As will be seen from the illustration the glass is so enclosed and centered in its housing that it is immune from breakage caused by expansion and contraction, and should the glass become broken maliciously or through some unusual accident, the metal netting encasing it renders injury from flying glass fragments impossible. Each gauge-cock fitting is equipped with a ball valve which closes automatically should the gauge glass become broken. The above fitting is made in steel for ammonia refrigeration work and in bronze for steam conditions.

The safety gauge glass is sold with gauge fittings complete and is also sold separately for insertion in any standard gauge fitting at present manufactured.

LOSS OF HEAT BY RADIATION

A UNIQUE test for determining loss of heat by radiation from boiler settings and steam drums has been run by Mr. C. A. Eastwood, superintendent of Station A, Pacific Gas and Electric Company, San Francisco, Cal. For his experiment Mr. Eastwood selected a 560 h.p. B. & W. boiler, the steam drums of which were covered with one course of common brick. A rectangular can containing a measured quantity of water was placed on top of one drum and the boiler was run at its rated capacity for a period of three days. During this time the rise in temperature of the water was carefully noted, and with these data it was a comparatively simple matter to determine: (a) the amount of heat radiated per square foot of surface per hour; (b) the amount of heat radiated from the total exposed area of the drums; and (c) the quantity of fuel which was being burned to make up for this loss. Mr. Eastwood's figures showed that the loss totalled 390 barrels of oil per year.

To determine how much of this fuel-loss could be saved by the use of an effective heat insulating material, one 2½-inch course of Nonpareil Insulating Brick, manufactured by the Armstrong Cork & Insulation Company, Pittsburg, Pa., was then placed on top of the common brick covering and readings were taken as in preceding tests. The result showed that with the Nonpareil insulating brick in place the loss of heat amounted to 144 barrels of oil per year —a saving of 246 barrels, or 63 per cent. With oil costing 70 cents per barrel, the saving amounted to $172.20 per year.

In considering these figures there are two points in connection with them that might be mentioned. First, the total amount of heat lost represents that radiated from the steam drums alone; second, only 2½ inches of Nonpareil brick were used. Had the radiation from the exposed boiler walls been included as well, the total heat-loss would have been considerably increased. Furthermore, if the common brick had been removed entirely and replaced with a course of Nonpareil brick set on edge, giving 4½ inches of insulation instead of 2½ inches, a still greater saving would have been effected, since, according to tests, Nonpareil brick are said to be ten times better heat insulators than either common brick or fire brick.

The "BULLDOG" Cleaner for straight tubes—3½ and 4 in. sizes

Engineer Duke was so sure of his "Bulldog's" ability that—

but read this fact story yourself

Frank K. Duke is a prominent Philadelphia engineer. At a plant near his own they decided to buy a boiler tube cleaner that was not a "Bulldog."

Mr. Duke had a "Bulldog" and to him it was the *only* tube cleaner worth having.

"Hold on!" he said to his neighbor. "Try another make of cleaner if you want to but try my 'Bulldog' in comparison with it—and don't buy before you do try."

He actually sent his "Bulldog" Cleaner over to them, loaned it to them for the trial—

And as usual, the "Bulldog" Cleaner proved its superiority. It emerged from that trial indisputably the winner.

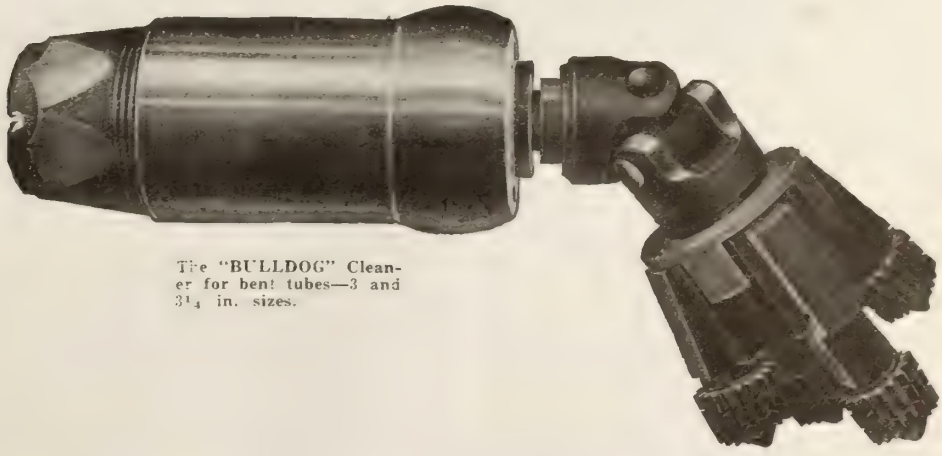
We don't know of any more convincing experience than this in proving not only that the "Bulldog" is as good a scale remover as you'll find anywhere, but also that no one appreciates that fact so well as the engineer who uses a "Bulldog." When are you going to purchase yours?

If you want some real definite information on scale fighting, send for our Catalogue "H." It describes the "Bulldog," also all types of Liberty Cleaners—a Cleaner for every purpose and every condition.

Liberty Manufacturing Company

6904 Susquehanna Street

Pittsburgh **Pennsylvania**



The "BULLDOG" Cleaner for bent tubes—3 and 3¼ in. sizes.

Trade Gossip

Mitchell, Ont.—The Town Council are contemplating installing a gasoline engine and pump.

Brandon, Man.—The City Council contemplate installing a new pumping plant at the municipal waterwarks.

Port Colborne, Ont.—Town Council contemplate the installation of a waterworks plant and pump equipment.

Port Colborne, Ont.—The Town Council contemplates the installation of a waterworks pumping plant and equipment.

Merritton, Ont.—The Riordon Pulp & Paper Co. will instal power equipment at the mill here. Head office, Montreal.

Nelson, B.C.—The Waneta Power Co. is engaged in the development of a large water power on the Pend d'Oreille River, south of Nelson.

Norwich, Ont.—Town Council propose enlarging the pump house and installing additional pump at a cost of $4,000. Engineer, F. J. Ure, C.E., Woodstock.

The Elliott Co., manufacturers of power accessories, have disposed of their office building in Pittsburg, Pa., and have taken a spacious suite of offices in the Frick Building in that city.

The Liberty Manufacturing Co., manufacturers of boiler tube cleaners, have removed their offices from Susquehanna street to the Frick Building, Pittsburg, Pa.

Airplane Engine a Success.—The first of one thousand aeroplane engines being built in Toronto was satisfactorily tested recently. The engines are being constructed at the plant operated by the Imperial Munitions Board.

Newboro, Ont.—A by-law has been passed giving the contract to J. P. Tett & Bros., for supplying electric light to the village. Power will come from Bedford Mills.

Penticton, B.C.—The City Council contemplate an expenditure of $20,000 for the construction of certain works in connection with the domestic water system and $35,000 for works in connection with the irrigation system.

Guelph, Ont.—Damage to the extent of about $3,500 was done by fire, smoke and water at the building owned by the Light and Heat Commission on Huskisson Street on Jan. 30. The loss is covered by insurance.

New Ross, N.S.—The mill and all the equipment of the Nova Scotia Manganese Co. at New Ross was completely destroyed by fire on Jan. 26. The loss cannot be replaced with less than $100,000 and there was only a few thousand dollars insurance.

Prince Rupert, B.C.—W. P. Hinton who was here recently, says that the Grand Trunk Pacific will spend $250,000 in Prince Rupert this year on a brick railway station to meet all requirements for ten years; machine shops and round house at Cameron Cove, and a 1,000-foot wharf.

Brantford, Ont.—Immediate Hydro power for Brantford Township has been promised the council of the municipality by Engineer Gaby, of the Ontario Hydro Commission.

Toronto, Ont.—The Ontario Wind Engine & Pump Co. has taken out a permit for the erection on the corner of Atlantic and Liberty Avenues of a steel and iron sila factory to cost $4,000.

Montreal, Que.—An influential deputation from Sault Ste. Marie, Ont., came to the city to interview F. W. Clergue, president of the Universal Transmissions, Ltd., regarding the construction of a shipbuilding yard and drydock at the Soo.

The Empire Waterworks Supply Co., of Winnipeg, has been awarded contracts from the Greater Winnipeg Water District for three 24-inch Rensselar gate-valves, all of the automatic air cluster valves and sluice gates, the latter being Coldwell and Wilcox.

Oxygen to Run Power Engine.—Production of motive power and light from the oxygen of the air at practically no cost except that of the original installation of the plant has been accomplished by Patrick K. Gallagher, of Nelson, B.C. For some years he has been working on his invention, and it has now reached the stage where he is developing an internal combustion engine, in which oxygen will take the place of gasoline, gas or oil.

Nelson, B.C.—The Waneta Power Co's big water-power plant on the Pend l'Orelle River, south of Nelson, is nearing completion. Preliminary construction work has been in progress for some years, though the company has but recently been incorporated, with a capital of $1,500,000. Power will be supplied to industries of both sides of the international border.

Ottawa, Ont.—The City Council has made application to the Ontario Municipal Railway Board for a hearing in connection with a by-law to raise by way of debentures $250,000 for the purpose of establishing a municipal fuel depot. The Board instructed the applicant city to first pass the by-law as proposed, when a date for the desired hearing will be fixed.

Nanaimo, B.C.—The Nanaimo Gas Co. has taken over the Nanaimo gas works, with W. W. Lewis in charge. Plans are already in hand for the improvement of the gas works on an extensive scale, which will place the works in a first-class condition. The plant that will be installed will be up-to-date in every respect and will be able to fill the wants of the city.

Vancouver, B.C.—A new and important canning industry is promised British Columbia if plans of the Dominion Canners, Ltd., of Hamilton, Ont., are consummated. Three sites here are now under consideration of the directors of the company, four of whom are now here personally looking over the ground with a view of establishing their second plant in British Columbia.

Niagara Falls, Ont.—The Hydro Commissioners of Ontario have agreed to let the City of Niagara Falls tap the new pipe which is being laid with a 24-inch main, which will give this city all the water it needs for many years to come. At the same time this will only be a temporary arrangement, as the city is negotiating with the Hydro for a permanent supply from the Power Canal being constructed.

Windsor, Ont.—It is likely that before long the Hydro Commission will purchase the Essex County Light and Power Co.'s plant and business. The plant is at present owned by the Detroit Edison Co. of which Alex Dow is president. This company supplies power to Windsor, Walkerville, Sandwich and Essex. Negotiations for the purchase have been proceeding for some months, but the deal has not been completed yet. The price will be likely around $200,000.

Niagara Falls, Ont.—Work is already well started upon the new pipe which is to supply 50,000 more horse-power for the Hydro. The pipe, which is 13½ feet in diameter, is to be run through Queen Victoria Niagara Falls Park. The work on the Chippawa-Queenston Hydro Canal is proceeding in spite of the severe weather, though it is exceedingly difficult to get men to stay on the job. As soon as weather conditions prove more favorable the Hydro engineers will put a new impetus on the job. The railway along the power canal is progressing and preparations are being made for dredging.

Hamilton, Ont.—The local Hydro Board has decided to reduce the power consumption here by the drastic method of cutting off non-essential industries one day a week. Hamilton is about 1,500 kilowatts short of its requirements, and it was thought that by cutting off certain industries rotation for one day a week this could be made up, and munitions plants and food-producing concerns could keep going without interruption. Several times of late all plants depending on Hydro have been cut off owing to this city having exceeded its limit, and it was thought this would be the most effective and most satisfactory way of meeting the situation.

Could Produce Much More Coal.—That the 10,000 miners of Nova Scotia could produce from 1,500 to 2,000 tons of coal more per day if "mechanical haulage" or more horses were used at the mines to remove the "mine boxes," was the statement of S. Barrett, President of the Amalgamated Mine Workers of Nova Scotia, who arrived in Ottawa on Monday to attend the joint conference of Canada's Labor delegates with heads of the Government. Mr. Barrett explained that he had come to Ottawa at the invitation of the Government to talk over increased coal production. He stated that it was his intention to bring to the knowledge of the Government the mode of mining coal, and he would suggest that more up-to-date methods be employed than having the men push out the mine trucks.

Brockville, Ont.—There are extensive peat fields adjacent to Brockville, which, if developed, would supply a want in the fuel shortage. Local interests have expended much in drainage and experimenting with drying processes without any material results. The Town Council is now petitioning the Ontario Government to take over the project.

Guelph, Ont.—A movement is on foot in this city to develop the unused power on the Speed River in the neighborhood of the Ontario Military Hospital. Several farmers have become interested in the scheme, with the hope that they may be able to secure power for use on their farms. It is understood that R. H. Clemens, district representative, is taking up the matter with the Hydro-Electric Power Commission, and an engineer will make an inspection soon.

Toronto, Ont.—Two whole townships, estimated to contain millions of tons of peat, have been set aside by the Ontario Government with a view to having them developed as a source of fuel for the province. The two townships are Hanna and St. John, lying on either side of the T. and N. O. railway, immediately south of Cochrane. In these townships, unsuitable for cultivation, examination has shown that the deposits of peat range in depth from six to forty or fifty feet in some places.

Chatham, Ont.—The Chatham Public Utilities Commission is considering the advisability of asking local manufacturers using Hydro power to operate their plants on night and day shifts in such a manner as to prevent any heavy peak loads at certain hours. The consumption of power in Chatham is considerably in excess of the allotment, resulting in the street lights being turned off at night and industries operating at night forced to economize. The normal consumption is 1,132 horse-power, while the city under the new orders is allotted 540 horse-power during the day and 940 at night.

Cornwall, Ont.—The St. Lawrence Power Co's. plant at the Sheiks Islands dam, which supplies electric power to several industries in Cornwall, is completely out of commission as a result of the high water. All local plants are shut down and this may last until the water recedes and repairs can be made. The water rose nine feet above the floor in the power house, putting the generators and transformers completely under its surface. Officials of the company stated that it would take at least a week to dry out their machinery and have it ready for action after the power house is cleared of water. The Stormont Electric Light & Power Co is doing all in its power to relieve the lighting situation in town by transferring their power wherever possible.

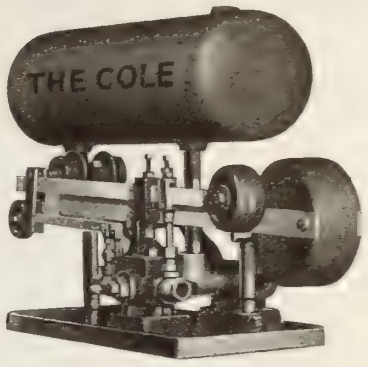
Saskatoon, Sask.—The contract has been let for the installation of the refrigeration machinery for the public co-operative cold storage system in Saskatoon being operated by the Saskatchewan Co-operative Creameries to the Canadian Ice Machine Co., of Toronto and Winnipeg. The total cost of the building and machinery will be about $125,000; of this amount the machinery alone will cost $60,000. The building has a total cold storage space of 206,000 cub feet. The machinery will comprise two 35-ton York compressors and condensers, electric motors, etc., equal to the cooling power of 70 tons of melted ice every 24 hours.

Niagara Falls, Ont.—Ice is causing considerable trouble in the power companies' plants here which has created a shortage of power for the Hydro-Electric Commission. The Hydro secures its power from the Ontario Power Co., the Canadian Niagara Co. and the Electrical Development Co. All these companies have had trouble with ice. One day recently there was a shortage of from five to ten per cent on the power from the Ontario Power Co. As the total capacity of the machines of this company is 160,000 horse-power this meant a shortage of from 8,000 to 16,000 horse-power. The amount of power that was available fluctuated throughout the day and at intervals of ten minutes there was only 50,000 horse-power available.

Gowganda, Ont.—The South Bay Power Co. will install a 500 h.p. electric unit and proceed with the diversion of the East Montreal River. The company fully expects to carry out its original plan, that is, to install a 1,500 electric horse-power plant at Hangingstone Falls, Gowganda Lake, for the purpose of supplying electric power to the mines at Gowganda. First, to install a 500-horse-power unit, part of the electric energy from same to be used to drive a tunnel to divert the East branch of the Montreal River into Hangingstone Lake, which will give water enough to develop an additional 1.000 horse-power. The Reeves-Dobie Mining Co. is assisting in the financing of the company for the purpose of securing electric power to operate their mine.

Sudbury, Ont.—The proposal of the British-America Nickel Corporation to secure Hydro power from a development plant on the French River has been definitely abandoned, owing to the prohibitive cost involved, according to a report current here. In consequence of this it is thought probable that the company will establish a refining plant in the neighborhood of Ottawa, where the Hydro-electric Commission has ample power at a low figure. Owing to the war all kinds of material have advanced in price, and it was estimated that power could not be developed on the French River under $40 or $50 per horse-power. The Hydro Commission, therefore, advised against the French River proposal and advocated the establishment of a nickel refinery in the Ottawa Valley. In the meantime, the British-America Nickel Corporation will likely install a steam plant at the Murray Mine to supply some of the power needed.

There is One Way to Save Fuel! Don't Burn It!



THERE is also another way to save it. That is by the installation of a "COLE" Return Trap System.

The fuel question is one of the most vital points in manufacturing to-day, and all means possible should be used to prevent its loss.

Send for a copy of our book "Steam Condensation," it may be of great help to you, and at any rate will cause no harm.

Remember! our engineering department is at your service.

POWER HOUSE

143-153 University Ave. Toronto

The Canadian General Electric Co. has secured the contract for the entire electrical equipment of the Bennett-Martin Asbestos and Chrome Mines at Coleraine, Que. The Canadian Wire & Cable Co. of Toronto, will supply the wire for the transmission system.

Winnipeg, Man.—At the meeting of the Greater Winnipeg Water District last Thursday afternoon, on learning that C. G. Anderson, owing to the alleged delay in granting the contract for the gate house and intake at Waugh, refused to do the work, Controller Wallace, seconded by Controller Cockburn, moved that the contract be granted to the next lowest tenderer, whose price was $97,000, while Anderson had tendered for $90,000.

Joint Commission to Prepare Report.—The International Joint Commission created by Canada and United States in 1911 to consider the developing of water-power and securing adequate sanitation in rivers and streams jointly controlled by the two Governments met in New York on Feb. 4 to prepare its final report which will be submitted to the Dominion Parliament and to Congress. The text of the report, it was announced, will not be made public until it has been approved by both governments.

Hamilton, Ont.—Tenders will be received by the Board of Control, up to Monday, March 4, 1918, for supplying the city with the following materials: Castings (ordinary and special), iron pipe, hydrants, valves, extension boxes, hardware, lead pipe, pig lead, road oil, lubricating oil, flux, fuel oil, lumber, gasoline, brass work, including ordinary and special brass castings for the Water Department. Specifications and form of tender for all of the above can be obtained at the office of the City Engineer, Hamilton, Ont.

Melbourne, Australia.—Tenders for the following may be addressed to the Director of Navy Contracts, Navy Office, Melbourne: Supply, delivery and erection at Garden Island, of one (1) 200 horse-power prime mover set of either semi-Diesel type or other heavy oil engine direct coupled to 2-65 K.W. 240 volt D.C. electric generating set. All accessories, tank and fittings to be supplied by tenders as per specification. Date of closing June 7, 1918. Tender forms are open for inspection at the Department of Trade and Commerce, Ottawa. File No. 20117.

The Canadian Crocker-Wheeler Co. of St. Catharines, Ont., whose fiscal year ended Dec. 31 last, reports a favorable condition of affairs in 1917 in comparison with the 1916 period. A new machine shop and power house were completed during the year and R. A. Stinson, the vice-president of the company, announces that the outlook for business in 1918 is most encouraging. They have recently completed the equipment and re-tooling of their ordnance department for the manufacture of 75 mm. French shells for the American Government. The contract for these shells will keep this department busy at least eight months.

CATALOGUES

What It Means To You is the title of a bulletin being distributed to the trade by the Dodge Manufacturing Co., Toronto. The bulletin deals with the principal features of the Dodge standard wood split-pulleys and contains an illustration showing their construction. The bulletin contains a list of firms in Ontario who stock the Dodge transmission equipment.

Pumps for Any Service is the title of an 84 page catalogue just issued by Darling Brothers Ltd., engineers and steam specialists, 120 Prince street, Montreal. It describes in detail, both in illustrations and text, the many and varied lines of pumps and compressors manufactured by this firm. It also contains several pages dealing with important information for the benefit of intending purchasers of pumps. The book is well gotten up and is a credit to Darling Bros.

New Catalog of "Beaver" Tools.—The Borden Co., Warren, Ohio, has just issued its 1918 catalog of "Beaver" easy working die stocks and square-end pipe cutters. This catalog is said to be the finest tool catalog ever issued, and its attractive appearance indicates that no expense has been spared in securing the services of the best artists and printers. This book is printed in two colors, on high grade paper, and illustrates in a complete and artistic manner the complete line of the "Beaver" product. Several new "Beaver" tools are shown for the first time in this catalog—one of the most popular of these being the new No. 3 "Beaver" Junior ratchet die stock, which is built on the unit plan to thread pipe from ⅛ in. to 1 in. inclusive. While this expensive catalog is not intended for general distribution, the Borden Co. will undoubtedly send a copy to any of our readers who will write a letter or card stating that they are interested in "Beaver" tools.

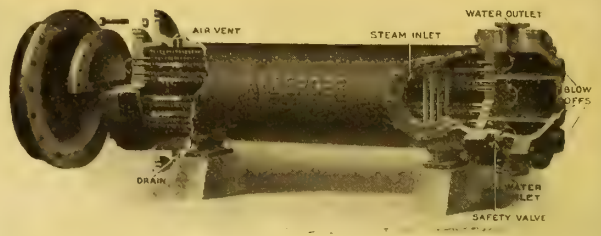
never fails to give long, satisfactory service, because it's made of those materials designed for extreme conditions.

THE CANADIAN FAIRBANKS-MORSE COMPANY, LIMITED.

CANADA'S DEPARTMENTAL HOUSE FOR MECHANICAL GOODS

For these reasons

the Alberger



is *without* usual heater troubles

1. Alberger "floating" heads into which the tubes expand at one end of heater prevent all expansion strain.

2. Alberger tubes are of pure copper. Brass, although a good conductor of heat, is subject to segregation of materials, with a consequent result of splitting under temperature changes when drawn into tubes. Copper, free from this objection because a homogenous material, will last indefinitely.

3. All water and steam connections are on the body of our special grade cast iron shell and these connections need not be broken to secure access to the heating surface.

4. Alberger tubes are small and corrugated: *Small* because usage shows that small tubes transmit a much greater quantity of heat per square foot of heating surface than large tubes; *Corrugated* because usage shows that corrugated tubes transmit over 50% more heat than plain tubes of the same size.

GRATON & KNIGHT
Standardized Series
LEATHER BELTING

Tanned by us for belting use

GRATON AND KNIGHT

Coal---Power---Belts---Production

YOU invest your money in coal to get power—POWER—the basis of production. If power leaks out in transmission, it **never** becomes production.

That is why selection of the belting that will transmit the greatest amount of power is a vital matter. It does not receive the careful study which it demands.

First: Use **leather** belting—the material that guarantees least power leakage; that is standard for main drives; that stands the mauling of shifters; that can be easily spliced and repaired; that when partly worn can be cut down for narrower pulleys; that has greatest elasticity and pulley-grip.

Second: Don't select belting on specification. Select it on scientific adaptation to the **work to be done.** Right here is the reason for the superiority of Graton & Knight Standardized Series Leather Belting.

Twenty mills with practically identical needs often specify twenty varied types of belting. And yet the requirements of power transmission fall into a relatively small number of classifications. For each of those classes there is a Graton & Knight Standardized Belt. Long study and experience fixed that standard and we keep it there—rigidly.

It will work an economy for you if you will let us specify the grade of belt for each pulley in your plant. Then, when you buy belting, call for "Graton & Knight———Brand or equal." This doesn't commit you to buying our belting. It puts your buying squarely and permanently on the only sound basis—the **work to be done.**

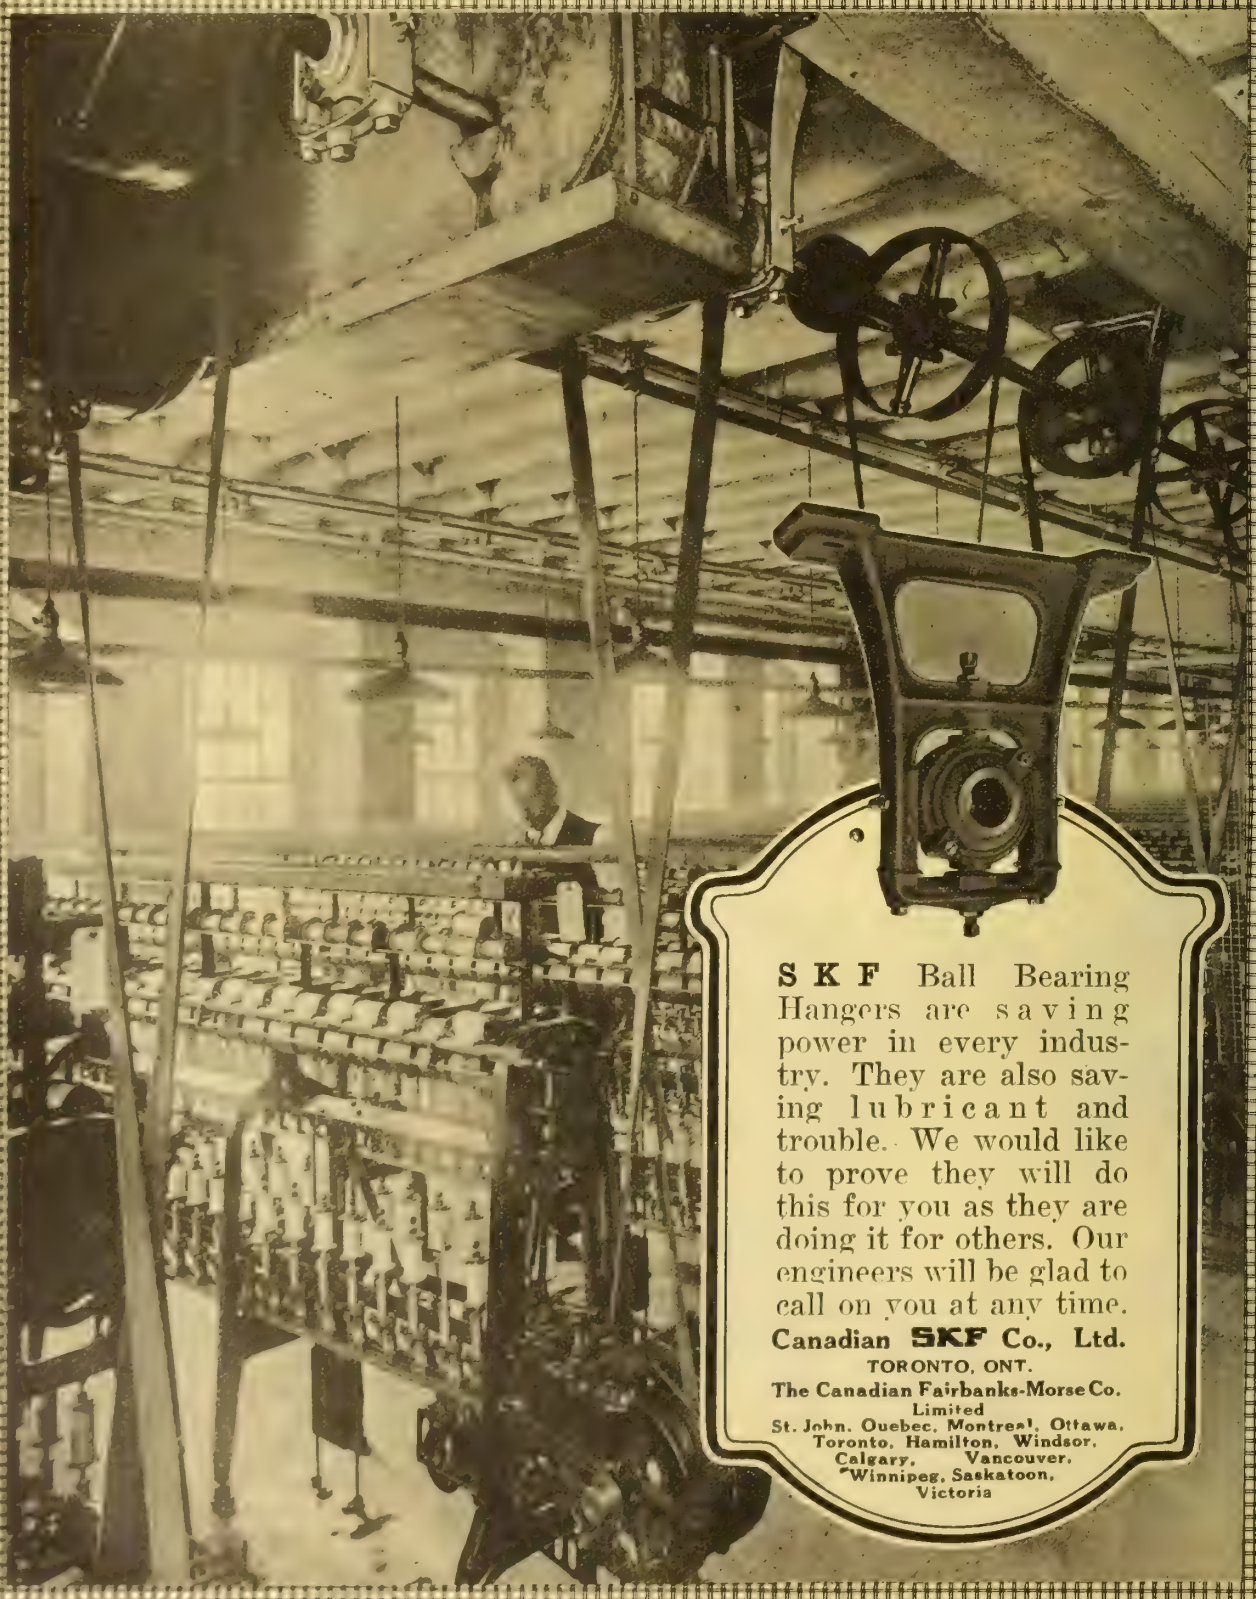
BALL BEARING HANGERS



S K F Ball Bearing Hangers are saving power in every industry. They are also saving lubricant and trouble. We would like to prove they will do this for you as they are doing it for others. Our engineers will be glad to call on you at any time.

Canadian SKF Co., Ltd.
TORONTO, ONT.

The Canadian Fairbanks-Morse Co. Limited
St. John, Quebec, Montreal, Ottawa, Toronto, Hamilton, Windsor, Calgary, Vancouver, Winnipeg, Saskatoon, Victoria

The function of lubricating oil is to give the greatest ease of motion to all parts of the engine, so that every possible atom of power may be transmitted to the machines. An oil that will do this will have effect on other divisions. Ease of operation would mean elimination of friction, no wear on the bearings, less oiling. Pure oil would be a decided labor-saving, cost-reducing, efficiency-promoting factor in the engine room. A great many Canadian manufacturers have pronounced our "Non-Corrosive Cylinder Oil" pure. We, who know its construction, pronounce it pure. Get in touch with us.

"Clean All" Feed Water Treatment

Your Boiler Troubles are Solved and the Solution is Genuine.

We guarantee that "Clean All" if used according to directions:

To remove (not dissolve) scale already formed, and to stop further formation.

To stop pitting, corrosion and minor leaks.

To be absolutely harmless to metals, packings and fittings.

To remove oil and grease, and increase efficiency of boilers 100%.

Submit samples of water used and all particulars of conditions of boilers, etc., and let boiler specialists diagnose your case.

SOLD IN 30 or 50 GALLON LOTS UNDER 60-DAY TRIAL.

CYLINDER LUBRICATION

A powerful microscope will disclose hundreds of irregularities on a bearing surface, no matter how smooth it may appear to the naked eye.

DIXON'S Ticonderoga Flake Graphite

will fill up these minute irregularities and form a smooth, durable veneer of graphite that is practically frictionless.

It will give better lubrication, cut the oil bills in half and eliminate wear and tear.

Send for Booklet No. 222-C telling more about this lubricant and method of successfully feeding dry graphite into cylinders

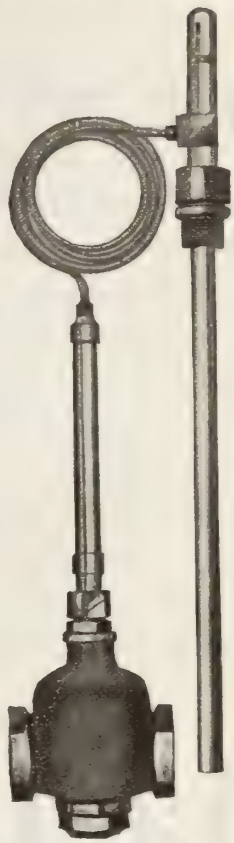
TEMPERATURE CONTROL



Vital as this may be to the final result in your manufacturing process-yet it is equally as important in the matter of fuel saving. Saving steam means fuel economy.

Why tolerate overheating when it represents fuel consumed and money lost with no direct benefit to your product?

Fuel economy is today recognized as an absolute necessity, and with the present high cost of steam many manufacturers and owners save the entire cost of installing SARCO TEMPERATURE REGULATORS within the first week or two. After that, this saving represents additional profit, and production is better.

The Sarco is small, simple in construction and automatically operated by its own hydraulic power.

Stop wasting steam—fuel and money. Get accurate temperature control and better your production.

A free trial will convince you of the merits of this simple and substantial Sarco Temperature Regulator.

We Are Losing The War!

OUR war aims have fallen from their original elevation. You may say they were too high at the beginning—when first formulated. Perhaps they were, but the real reason for their toning down, as Colonel John Bayne Maclean sees it, is because we have lost many things to Germany which can never be recovered—and lost them by the bungling of incompetent Cabinet Ministers. He instances the failure to make contraband cotton in 1914, when, had this war material been made contraband, the war might have ended in the year in which it was begun. He instances the Dardanelles fiasco which almost drove Australia out of the war. Colonel Maclean shows how Russia might have been saved as an aggressive ally, and how Bulgaria might have been made an ally at the cost of a million dollars. It is startling material which Colonel Maclean provides, and will cause world-wide discussion. We are losing the war, he affirms, but he does not say we have lost it. How it can be won he tells also. Read what he has written in

MacLean's Magazine

for FEBRUARY

In this issue are short and long stories by Alan Sullivan, E. Phillips Oppenheim, Archie P. McKishnie and Ethel Watts Mumford. There is a war poem by Alfred Gordon. The special Business articles which are a feature of every issue of MACLEAN'S MAGAZINE, and the department of Women and their Work, are present.

The Review of Reviews Department contains satisfying presentations of literary and descriptive articles taken from the leading magazines of the world. The story of Hon. Henri Beland, Canadian prisoner of war in Belgium, is told in this number of MACLEAN'S MAGAZINE. There are biographical sketches of Thomas Findley, President of Massey-Harris Company, and of George J. Desbarats, C.M.G., who has done so much for Canada's development of her Naval service.

MUELLER

Globe and Angle Valves

BUILT from actual, practical experience. Made of the famous *MUELLER* steam metal and fully guaranteed against all defect in design and construction. Not a Valve, but *the* Valve.

¶ *MUELLER* globe and angle Valves can be repacked under pressure. The disc is so designed as to adjust itself to any position and still receive the thrust of the spindle on the center line; thus preventing any distortion to the seat or diaphragm. The pipe threads are full length, and are tapered to conform to I. P. Threads, insuring perfect joints.

¶ Full sized and unobstructed passages guarantee full service. The large Hexagons allow an excellent wrench grip and our design puts the strain where it belongs, so that there is no danger of distorting either the body or the bonnet. Furnished with enameled, Malleable iron wheel handles. Every *MUELLER* Valve tested to beyond unusual service conditions. Write for prices.

MUELLER **gate and check valves, steam cocks, etc. rank highest in every branch of exacting service.**

TRADE JENKINS MARK

Jenkins Bros.

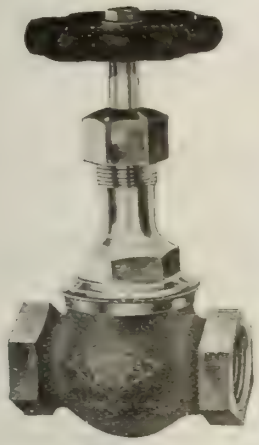

FIG. 106

FIG. 108

Why Jenkins Bros.' Valves are Superior

THEY are the original renewable Disc Valves. They have more imitators than all other makes of valves combined. They have kept pace with increasing steam pressures and severe working conditions. They are of the simplest design, and can be easily repaired by any man of ordinary intelligence. They are made interchangeable in every part, and any part can be duplicated promptly and inexpensively either by the dealer or through the nearest Jenkins Bros.' branch, where large stocks of duplicate parts are constantly kept. In the majority of cases they can be repaired by merely changing the disc without the laborious task of regrinding.

They are recognized as the Standard Steam Valves in all parts of the World, and wherever there are supply houses—Jenkins Bros.' Valves will be found. The Standard of quality never changes except to improve, and while to-day there are hundreds of imitators, the sales of genuine Jenkins Bros.' Valves are constantly increasing.

Jenkins Bros.' Valves are approved for use in Ontario and the Western Provinces by the Depts. of Public Works. Stocked by first-class dealers everywhere.

Becoming a Bigger Man

WHAT is the difference between some men you know and others known to you? Why are some men earning $3,000 a year and some $30,000? You can't put it down to heredity or better early opportunities, or even better education. What, then, is the explanation of the stagnation of some men and the elevation and progress of others?

We are reminded of a story. A railroad man, born in Canada, was revisiting his home town on the St. Lawrence River. He wandered up to a group of old-timers who sat in the sun basking in blissful idleness. "Charlie," said one of the old men, "they tell me you are getting $20,000 a year." "Something like that," said Charlie. "Well, all I've got to say, Charlie, is that you're not worth it."

A salary of $20,000 a year to these do-nothing men was incredible. Not one of the group had ever made as much as $2,000 a year, and each man in the company felt that he was a mighty good man.

Charlie had left the old home town when he was a lad. He had got into the mill of bigger things. He developed to be a good man, a better man, the best man for certain work. His specialized education, joined to his own energy and labor sent him up, up, up. To put it in another way: Charlie had always more to sell, and the world wanted his merchandise—brain, skill and ability. Having more to sell all the time, he got more pay all the time.

Charlie could have stayed in the old home town; could have stagnated like others; could have been content with common wages. In short, Charlie could have stayed with the common crowd at the foot of the ladder. But Charlie improved himself and pushed himself, and this type of man the Goddess of Fortune likes to take by the hand and lead onward and upward.

Almost any man can climb higher if he really wants to try. None but himself will hold him back. As a matter of fact, the world applauds and helps those who try to climb the ladder that reaches towards the stars.

The bank manager in an obscure branch in a village can get out of that bank surely and swiftly, if he makes it clear to his superiors that he is ready for larger service and a larger sphere. The humble retailer can burst the walls of his small store, just as Timothy Eaton did, if he gets the right idea and follows it. It is not a matter of brain or education so much as of purpose joined to energy and labor. The salesman or manager or bookkeeper or secretary can lift himself to a higher plane of service and rewards if he prepares himself diligently for larger work and pay. The small manufacturer, the company director, the broker—all can become enlarged in the nature of their enterprise and in the amount of their income,—by resolutely setting themselves about the task of growing to be bigger-minded men.

Specialized information is the great idea. This is what the world pays handsomely for. And to acquire specialized information is really a simple matter, calling for the purposeful and faithful use of time. This chiefly.

One does not have to stop his ordinary work, or go to a university, or to any school. One can acquire the specialized information in the margin of time which is his own—in the after-hours of business. Which means: If a man will read the right kind of books or publications, and make himself a serious student at home, in his hours—the evening hours or the early morning hours—he can climb to heights of position and pay that will dazzle the inert comrades of his youth or day's work.

IF business—BUSINESS—is your chosen field of work, we counsel you to read each week THE FINANCIAL POST. It will stimulate you mentally. It will challenge you to further studious effort. It will give you glimpses into the world of endeavor occupied by the captains of industry and finance. With the guidance of the POST, and with its wealth of specialized information, you, a purposeful man, aiming to go higher in life and pay, will find yourself becoming enlarged in knowledge and ambition, and will be acquiring the bases and facts of knowledge which become the rungs of the ladder you climb by.

It is the first step which costs. But this cost is trivial—a single dollar. We offer you the POST for four months for a dollar. Surely it is worth a dollar to discover how right we are in our argument. If you have the will to go higher in position and pay, sign the coupon below.

THE MACLEAN PUBLISHING COMPANY, LIMITED,
143-153 University Avenue, Toronto.

Send me us THE FINANCIAL POST for four months for one dollar.

Money to be enclosed remitted.

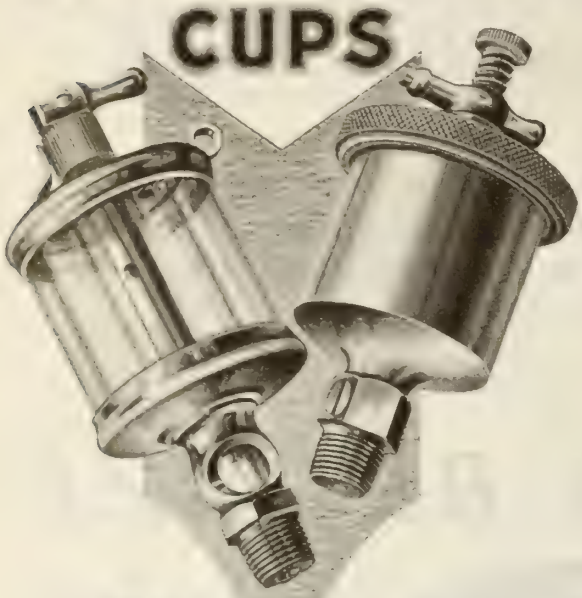
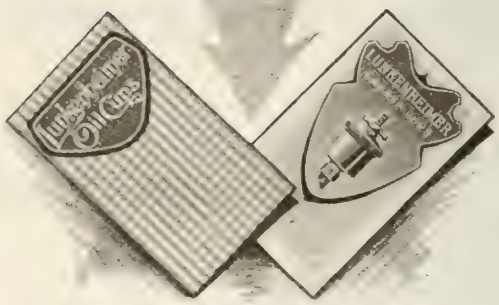
LUNKENHEIMER
OIL AND GREASE CUPS





For Engine AND Transmission Bearings

By their unfailing reliability have won the reputation they enjoy. The engineer specifying "Lunkenheimer" **knows** that bearings thus equipped will get the amount of lubricant for which the feed is set—**uniformly**, until cups are empty, and that no further attention is necessary other than filling.

They are practical and durable; the feed regulation is simple and easily adjusted, and there is no danger of unsetting the feed when refilling.

The variety of types made embraces **Oil Cups** with Glass or Bronze Body, with or without Sight-feed; and **Grease Cups** of Bronze, Iron and Steel, with Screw or Spring Compression Feed—a type for every service requirement.

"Write [illegible] equipped" in your engine and transmission specifications, and insist on having the genuine. Descriptive Booklets Nos. 523 and 524-DC will assist you in [illegible] the proper type. Write for copies.

Oil Filtering and
Circulating System

Results that Count

The Bowser System makes good results a sure thing.

Wherever it is installed there is more uniform lubrication of machines, without loss of oil; less depreciation of equipment; fewer repair bills; a better spirit among employees, and—increased profits, all of which are good, strong reasons why the Bowser should be in your plant.

The Bowser stores and supplies new oil—collects dirty oil—purifies it, makes it good as new—returns the proper supply to points of use wherever located. Its simplicity, durability, and ease of operation are reasons for its popularity in all well regulated plants.

"Results that Count" always follow its use—we'll be glad to tell you more about it if you drop us a line.

Canuck Supply Co., Limited

Toronto Montreal Winnipeg

All Down the Line—

You'll find sizes and types of

Jefferson Unions

for every union need—why not standardize them and put an end to pipe line troubles throughout your plant?

The Jefferson feature of forcing the brass seat ring into a recess just back from the runway and contents of the pipe makes it corrosion-proof and at the same time much more durable than a bronze or brass seated union handled in any other way. Then the weight of a Jefferson is greater than any other union of similar class—another logical "reason why" they are most successful.

If your jobber can't supply Jeffersons, a line direct to us will bring you the name of our nearest dealer and the Jefferson Book "Unions"—a treatise on pipe line connections which you'll enjoy reading.

Jefferson Union Features

Ground ball brass-to-iron or iron-to-iron joint, ground with mate and never separated.

Sloping shoulder and large play in the ball end, which is of assistance in connecting piping out of line.

Standard pipe threads tapered to fit the pipe. Coarse nut threads for quick adjustment.

Heaviest of its class made and sold at reasonable prices.

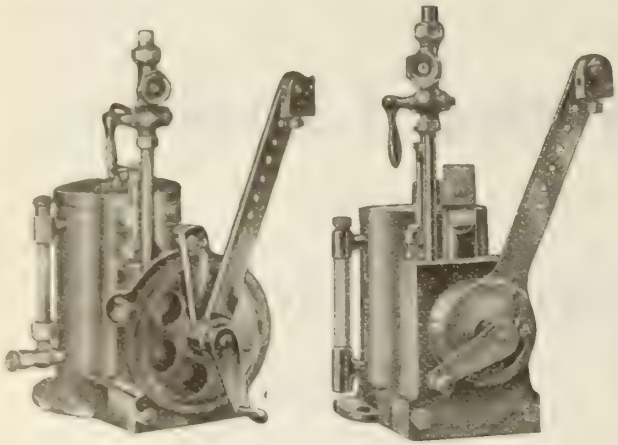
The Rochester Automatic Force Feed Lubricators



Ratchet Drive Pattern Clutch Drive Pattern

Force feed lubrication is acknowledged to be the only correct method for lubricating the cylinders of all types of engines, pumps and air compressors, so that there is no need for any argument in its favor.

We recently received an unsolicited testimonial from the Chief Engineer of an Ontario Municipal plant in regard to a Rochester Lubricator. This is extremely unusual—if we were manufacturing patent medicines, unsolicited testimonials would be expected, but seeing that we are engineers, whose business it is to manufacture Pumps, Elevators, and Steam Appliances generally, why, a testimonial, especially one like this is something to be proud of.

This Engineer goes on to say:

. . . . . "I admire the Rochester Lubricator from the standpoint of simplicity, reliability, excellence of workmanship, and good materials. . . . suffice it to say, I know a good thing when I see it, hence I would not have ordered ANOTHER Rochester had it not been a satisfactory lubricator."

Note he says "another," and he tells us that this "other" has been in use for **twelve years and still going strong.**

It's too bad that we are unable to print this engineer's name and official capacity—he objects to publicity. We have it on file at our head office for reference, if necessary.

After all this is only another proof of the excellence of our products.

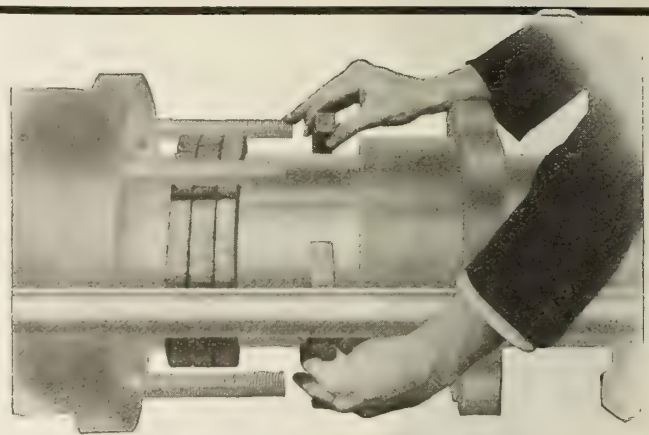
CANADIAN DETROIT LUBRICATOR COMPANY, LTD.

WALKERVILLE, ONT.



WHY YOU SHOULD USE "JOHN CRANE"

FLEXIBLE METALLIC PACKING

1—**SERVICE:** Packing steam, air, water, oil, ammonia, gas, etc., right from same coil. Think of it!

2—**STOCK:** A coil of 1/8, 1/4, 3/8, 1/2 and 5/8 absolutely protects you against shut-down. Any coil can be formed 1/16 smaller or larger with ease.

3—**TEMPERATURE:** Heat kills fabric packing, but has no effect on metal. Hence "John Crane" permanency.

4—**PRESSURE:** These flat metal sheets are ideal barriers for pressures. Resists up to 5000 pounds.

5—**FLEXIBLE:** All metallic, yet bends easily, taking any form or shape under pressure.

6—**NO SCORING:** It is a well-known fact that a good, well babbitted bearing will never score a shaft, neither will a good babbitted packing—in other words "John Crane" packing.

7—**PERMANENCY:** Five years on outside packed plungers, accumulators, presses, rods, shafts and stems justifies its general adoption.

8—**EASILY ORDERED:** If you want to pack, you do not want to order THIS KIND FOR THIS KIND OF SERVICE and THAT KIND FOR THAT KIND OF SERVICE. All you need to do is to order "John Crane" for everything.

Put your packing troubles up to us. This metallic Packing is not only DIFFERENT, but FAR BETTER. Get our Bulletin No. 1 for special services.

Crane Packing Company - Box 241, Windsor, Ont.

General Office and Factory, Chicago, Ill.

JOHNS-MANVILLE
Service to Power Plants

Increasing Power Output—by Reducing Friction

TO the engineer the very names "packing" and "stuffing-box" tell an interesting story. The sole function of rod packing is to prevent leakage. Until recently this has been accomplished, for a time at least, by filling the stuffing-box solidly with packing, screwing up the gland or allowing the packing to expand until its pressure on the rod was sufficient to hold back the steam or liquid attempting to escape.

This prevented leakage—but it cost money in three directions: heavy wear on packings, wear of the rod, and loss of power through friction. And the last is especially important if you consider that every foot-pound of energy consumed in plant operation directly reduces the surplus of power available for sale or for factory use.

So we set out to reduce friction and wear of rods and packings at no sacrifice of steam-tightness—and by solving the problem we have inaugurated a new era in "Stuffing-Box Engineering."

Johns-Manville Sea Rings are automatic and active, instead of inert. The pressure of the fluid against the packing holds the lip of the ring tight against the rod—and when pressure falls off or is on the opposite side of the piston, the packing relaxes and permits the rod to move freely. So friction is saved, and power—and the wear on packing and rod is less.

And Sea Rings are but one item in the standardized list of Johns-Manville Packings—a packing for every requirement. Each Johns-Manville Packing is different—with a sound engineering reason for the difference. They're designed to *wear*, and to save money and power—and we back each one to the limit.

You can prove it for yourself by investigation, almost anywhere, or by test—and we'll be glad to help you.

THE CANADIAN H. W. JOHNS-MANVILLE COMPANY, LIMITED

MONTREAL TORONTO VANCOUVER WINNIPEG
LONDON HAMILTON OTTAWA

Canadian Association of Stationary Engineers

Incorporated May, 1887 — Incorporated at Ottawa, June, 1917

An organization having as its aims and objects:—

To promote the knowledge of its members in the art and science of Steam Engineering.

The dissemination of information beneficial to the members of the association in the discharge of their calling.

To further and protect the interests of competent engineers, and receive such as members of this organization.

To secure, through proper legislation, the greatest security in operation of steam plants.

To assist unemployed members to secure positions.

To maintain freedom of action between employer and employee.

The members of the Association subscribe to the above in the full belief that ability and knowledge of one's profession are necessary to insure the highest degree of success.

Labor Study Energy

These three essentials have been responsible for the success of the world's greatest men. They are no less essential for yours. We cannot all become great, but this fact does not lessen the necessity for the exercise of these essentials in our individual occupations. Cool, calm, calculating judgment characterizes the successful power house operator of to-day. The demands on the engineer of to-day are many, and the obstacles in his path are great. To assist in the overcoming of these and help the accomplishment of great works, material, moral and educational, is the desire of all our members.

The benefits accruing from association with members of his fraternity, the opportunity to benefit by their experience, and the inspiration to greater effort by reason of their success render membership in this association indispensable to all progressive engineers.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

J. H. HALE, General Secretary, C.A.S.E.

230 Caroline Street — Hamilton, Ont.

D. K. McLaren's

Belting shows what a farce is the common theory that only by extraordinary tension can a belt get adequate pulley grip. It stands to reason that extraordinary tension **plays particular havoc** with belting. It strains shaftings and wears out bearings. Nothing so well supports our contention as actual comparison of the service and length of service life of other belting with that of D. K. McLaren's

Genuine British Oak-Tanned
Leather Belting

D. K. McLaren's Belting—amply flexible and really nearer to stretchless than any other belting made—hugs the pulley with a grip that never slips. It renders the service **you ought to demand.**

Everywhere in Canada are enthusiastic users of D. K. McLaren's Belting. Let us put you in touch with several in your own town. Write to-day.

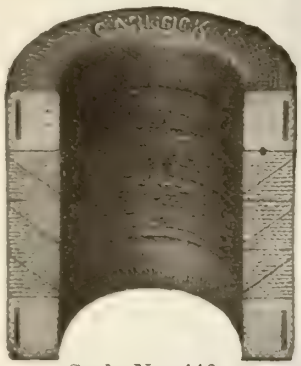
GARLOCK PACKINGS

Style No. 200

High Pressure Packing will give reliable and efficient service without injury to piston rods, because it is thoroughly lubricated throughout every fibre, and the material, design and workmanship are unequalled.



Style No. 446

Medium Pressure Duo is a combination of high pressure and diagonal rings put up in sets to exactly fill stuffing box. The diagonal rings adapt themselves automatically to rods not running true, while the high pressure rings bear the brunt of the pressure and heat at bottom of stuffing box.

Style No. 950

Style No. 950 Gaskets are cut from Superheat Sheet Packing, which is made of the best quality of long fibre asbestos, built up under tremendous pressure, thus securing great tensile strength. They are not affected by extremely high temperatures, and being of a tough, non - vulcanizing material, do not need following up after being applied.

For Packing

High Pressure Steam Rods
Use Garlock Style Number 200

Medium Pressure Steam Rods
Use Garlock Style Number 446

Low Pressure Steam Rods
Use Garlock Style Number 333

Worm or Scored Piston Rods
Use Garlock Style Number 336

Cold Water Piston Rods
Use Garlock Style Number 99

Inside Packed Plungers
Use Garlock Style Number 260

Outside Packed Plungers
High Pressure Cold Water
Use Garlock Style Number 960

Outside Packed Plungers
High Pressure Hot Water
Use Garlock Style Number 1907

These Packings are guaranteed to give satisfactory service under the above conditions.

The Garlock Packing Co.

HAMILTON, ONTARIO

BRANCHES:

MONTREAL - - -	409 Shaughnessy Building

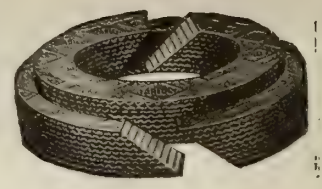
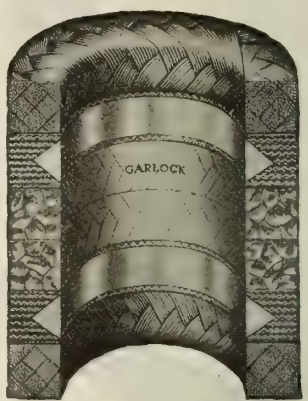
WINNIPEG - - - - - - -	Galt Building



Style No. 336

Extra Sectional Ring while designed principally for worn or scored rods will give excellent service on any medium or low pressure steam rod when used alternately with solid Extra Rings, Style No. 333.



Style No. 960

Duo Hydraulic is composed of braided copper, metal wedge and waterproof hydraulic rings, and is best adapted to meet the varying conditions and temperatures to which hydraulic packing is subjected. This combination will hold a pressure of three thousand pounds.

Style No. 260

Special Hydraulic Solid Rings for plungers of inside packed pumps are unexcelled for durability and satisfactory service. They are also used in combination with our other packings for outside packed plungers working either in hot or cold water.

Albany Grease

has just rounded out a half century of usefulness. Its incomparable record of lubrication service during the past 50 years stamps it as a most efficient and economical lubricant. For

50 YEARS

Albany Grease has been used by engineers on the bearings of engines, motors, pumps, compressors, line shafting and all their other equipment. If you are not using Albany Grease send for samples and try it.

Dont Claim Exemption

—because the air is filled with dust,
—because this dust settles on the belts,
—because it makes a belt dressing "ball up"
are no reasons at all why your belts can't have the benefit of

CLING-SURFACE Belt Preservative

Just wipe the dust off first.

Then with the swab (as shown) treat the face of the belts **a little at a time.**

Your belts will absorb CLING-SURFACE very quickly, leaving a clean, **not sticky,** surface.

It will be smooth, velvety, and will not slip.

Nor will it hold the dust.

Your drives will last longer, do more work, cause no trouble, and can be run easy or slack under full loads.

They will never again have static electricity.

* * *

Results like these PAY.

Are you willing to try this treatment if such trial **costs you nothing?**

Then write to-day for the 25-pound can we have waiting for you.

Use it sixty days.

If you're satisfied, pay us for it. If not, we will take back what you have left, charge you nothing for what you've used, and pay the freight both ways.

ALL CHEERFULLY—no hard feelings!

Remember, use CLING-SURFACE and you won't need belt dressings.

BEST BY TEST

GRAND TRUNK PACIFIC ELEVATOR CO., LTD.

Fort William, Ontario, Can., 2/8/17

Magnolia Metal Co.

Gentlemen:

I have made comparative tests with Magnolia and other so-called better grades or higher priced metals, and after the severest tests I was able to subject them to, I am able and pleased to say that Magnolia gave the best results

These tests were of several years' duration and our electrician and millwrights took particular pains to make notes on these tests as well as myself. We use both oil and grease and have equally good results with both.

Our motors vary from 6 H.P. to 100 H.P., and in speed from 415 to 1,200 R.P.M. My experience with Magnolia Metal extends over a period of 25 years and might be termed a hide-bound Magnolia Metal user, and am ready to plead guilty.

I do not hesitate in stating that for reducing friction, obtaining long life, and securing an easy mind for the engineer, electrician and millwright, I have not found a metal equal to your Magnolia Metal.

Yours truly,
M. F. BUYER, Supt.

ALWAYS ON THE JOB

Day after day Morse gets the Chicago Tribune "out on time"

The number of publications which depend upon MORSE SILENT CHAINS to turn out their issues is indeed significant. Among the better known are The New York Times, The Chicago Tribune (whose big drive is pictured here), the Ed. Langer Press, The Kansas City Star and The McCall Presses.

Big publications require the surest and most reliable power transmission obtainable behind their enormous plants. There can be no guesswork, no experimentation. They demand a drive which can be absolutely depended upon day after day. There is but one answer—

MORSE SILENT CHAINS

NOTICE

TO

Stationary and Hoisting Engineers

Everyone operating a STATIONARY steam plant of 50 h.p. or over in the Province of Ontario must hold a Stationary Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse power, and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Application forms for obtaining STATIONARY or HOISTING Engineers' Certificates, may be had upon applying to the Chairman.

HON. F. G. MACDIARMID, Minister of Public Works and Highways. W. C. McGHIE, Chairman of Board.
W. A. RIDDELL, M. A. PH. D., Superintendent, Trades & Labour Branch.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914 With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID, Minister of Public Works and Highways
W. A. RIDDELL, M.A. Ph.D., Supt. Trades & Labour Branch

D. M. MEDCALF,
Chief Inspector of Steam Boilers.

The Wrench of 25% Greater Efficiency

TRIMO PIPE WRENCH

Two new features have been recently added to the Trimo Pipe Wrench, namely Nut-Guards, in all sizes, and unbreakable steel frames, in leading sizes.

The Nut-Guards prevent the accidental rotation of the nut while in use.

These improvements add 25% to the usefulness of the tool.

The Trimo Pipe Wrench is made with wood handles in 4 sizes, 6-in., 8-in., 10-in., 14-in. and in steel handles in all sizes, 6-in. to 48-in. inclusive.

All Trimo Pipe Wrench parts are interchangeable.

The inserted jaw in the handle can be readily replaced when worn, thus adding to the life of the tool.

Nut with Nut-Guards

Use Much Less Fuel

You can save yourself and Canada 8 to 20% of the fuel you use to-day. You can make your steam heated equipment produce up to 50% greater volume.

This Morehead Back-to-Boiler System takes the condensation from steam lines and returns it to the boilers as pure HOT feed water.

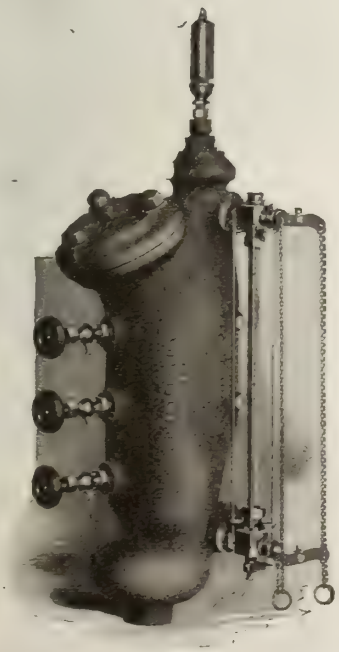
172 John St., Toronto

Water Neared the Danger Zone



The engineer was oiling. No one was near the register. The water dropped lower.....lower. Trouble seemed inevitable. Then—*in time*—

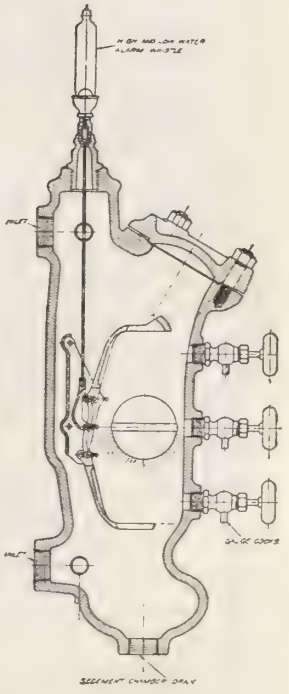
Anderson Water Column

Sounded the Alarm

The engineer, before the alarm sounded, never gave a thought to whether the boiler water was rising above or falling below danger level. His whole attention was given to the work of the moment—*as it ought to be.*

It is this feeling of security, this subconscious awareness of perfect protection, that moves users of the Anderson Water Column to speak enthusiastically of it.

Write us for full details and names of users.



The V. D. Anderson Company

1935 West 96th St., Cleveland, Ohio

Wanted—

Engineers to contribute to Power House

THIS is a practical paper for practical engineers. It is an educational medium and out to help its readers. It is a technical school and a social meeting place combined. It is first, last and all the time an engineer's paper.

If you should meet two or three or a dozen of your brother engineers you would swap ideas—you'd tell of some idea you had worked out in your plant. Others would describe some pet schemes they had devised. And so you would be mutually benefited.

Why not make Power House your monthly meeting place? Why not describe in this paper some kink or scheme you have worked out and found successful? We will pay you for it and you, in turn, will be multiplying the usefulness of your idea five thousand fold!

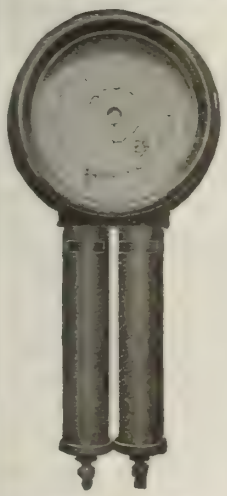
Never mind polishing up your letters—just give us the idea; that's the main thing. Never mind how crude your pencil sketch may be. We have draughtsmen who will finish up your drawings so they may be reproduced.
Try this idea a time or two and see how much satisfaction you'll get out of it. Start the ball a-rolling and thus help other engineers, yourself and your paper.

POWER HOUSE, 143-153 University Avenue, Toronto

UEHLING WASTE METER

COMBINED

CO_2 AND TEMPERATURE RECORDER



Record of CO2 and stack temperature on one chart.

Does your fireman know how much fuel he is wasting? Do you know?

The Uehling CO_2 Recorder makes a complete 24 hr. record of your combustion efficiency and the CO2 indicator at the Boiler Front holds the fireman responsible.

Get more Steam per pound of Coal and reduce your annual fuel consumption.

Let us know the number and size of your boilers and coal consumed per year, upon receipt of which information we will be glad to send you full particulars.

CO2 Indicator for Boiler Front

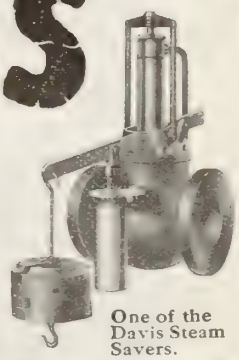
Let us hear from you. We are pioneers in the manufacture of Indicators and Recorders for Power Plant purposes.

Send for our Bulletin No. 110.

Uehling Instrument Company

2008 Empire Building New York City

DAVIS



One of the Davis Steam Savers.

PRESSURE REGULATOR

Correct Pressure and Uniform Pressure Insure Efficient Operation—

And that means the Davis.

It is built like a pair of balance scales. The steam pressure inside is balanced by weights on the outside—the action is just as visible and accurate as the action of a pair of balance scales.

No spring pressure to vary, no packing to interfere with proper action, no delicate parts needing attention and adjustment.

Simple and positive in action as the law of gravity—because it is controlled by gravity.

G. M. DAVIS REGULATOR Co

434 MILWAUKEE AVE., CHICAGO

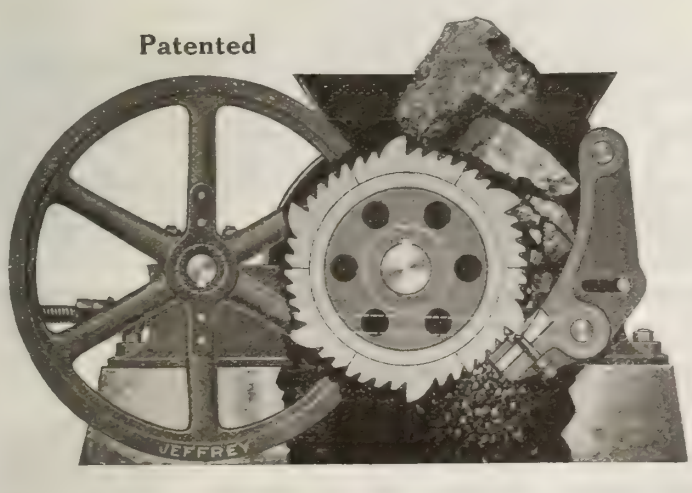
SUNDAY DISPATCH. SUNDAY, OCTOBER 7, 1917.
Shortage of Electricity
For Power, Light and Street Railway Purposes
Electric Power Shortage
The electric power situation in and the surrounding territory served by this company has become more acute. This is due to the fact that the existing equipment in our power stations cannot be operated at its full capacity because we have been unable to procure a good grade of coal. However much we may regret our inability to meet the demands upon us—and we most certainly do regret it—the situation must be squarely faced and steps taken to conserve the supply of electricity.
We request those who use electricity for power purposes to give their most earnest consideration to ways in which they can saving of current in their business.
who use electricity for lighting fewer lights. Use only were used.
Our Coal Troubles
The coal we are now receiving is of the most inferior grade we have ever had experience with. Our firemen jokingly refer to it as "fireproof" coal because it is so full of dirt that it will barely catch fire. In fact, some actually had corn growing in it as it stood in the car when received, and tests made of the coal have shown it to contain as high as 26 per cent. of non-combustible material.
It has been due to this fact that several times recently we have been forced to discontinue service to power customers, to operate cars at half speed for short periods and to operate a reduced number of trip-per cars during the rush hours. The poor grade of coal makes it utterly impossible to operate our boilers at capacity and lowers the output of our power station system.
Our Plans to Improve Service
With a view to bettering the fuel situation in our power stations we have acquired the use of a crushing plant in the city which will enable us to reduce to smaller sizes for use in our stokers lump and run-of-mine coal, and we have men continually in the coal fields using all their efforts to secure such coal.
The present serious situation prevails throughout the country—this community is not alone in difficulty, but this company, without help, can not attain the desired results. Relief can come only with your immediate and persistent co-operation.
Power & Light Co.
A Jeffrey Single Roll Crusher

Are You Facing a Similar Situation?

If so, why not Crush your Run-of-Mine or Lump Coal right in your own Power House with a

Patented



JEFFREY

SINGLE ROLL

Coal Crusher

One operation reduces Lump or Run-of-Mine Coal to the proper size for maximum heat efficiency in stokers.

Bulletin No. 141-4 fully describes this machine — tells what it has done for others. Send to-day for your copy.

Don't buy that New Electrical Apparatus Just Yet

WE can supply you with high-grade apparatus that has been slightly used and discarded through no fault of its own, at an **immense saving in cost.** For instance, in many cases we take over entire plants simply because of changed conditions such as increased capacity, change of system, etc.

EVERYTHING IS OVERHAULED AND REFINISHED BY US AND **GUARANTEED** AS GOOD AS NEW, BOTH ELECTRICALLY AND MECHANICALLY.

Our catalogs of offerings should be in the hands of every power plant superintendent each time they are gotten out, and it will be worth while for anyone interested in this class of power plant equipment to be on our mailing list to receive all offerings.

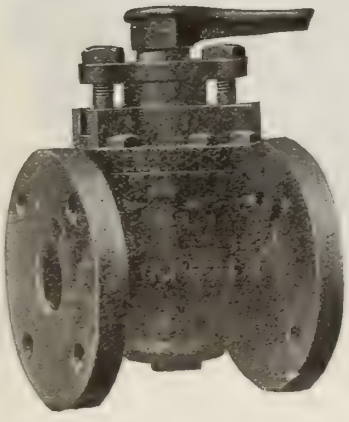
Nearly all of the principal power, lighting and street railway plants in the United States are our customers.

WRITE FOR OUR LATEST CATALOG of **Power House Equipment, Street Cars, Motors, Hoists, Compressors, etc.**

MACGOVERN & COMPANY, Inc.

114 Liberty St., New York City

Little Leaks Must Stop



Yes—It will mean endless watchfulness as long as ordinary valves are used.

But—Consider the economy of better valves.

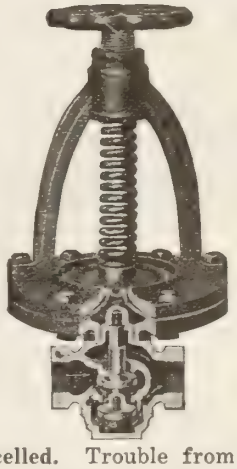
Homestead Quarter Turn Valves

Stop leaks permanently. They last several times longer than ordinary valves. Consequently the economy of using Homestead valves on all your pipe lines—and particularly on those that are now most troublesome—is obvious. Convince yourself with one Homestead Valve on trial. **Write:**

Homestead Valve Mfg. Co.
HOMESTEAD, PA.

CURTIS Engineering Specialties

CURTIS Water Pressure Regulator



The Economy of this Curtis Water Pressure Regulator (See Illustration) lies in the fact that it greatly reduces the cost of keeping plumbing in order — This by obviating the wear and tear of water hammer or concussion in pipes.

This regulator is warranted to maintain the pressure desired, **with perfect uniformity, regardless of any fluctuations of outside pressure.** The workmanship and material of the Regulator **cannot be excelled.** Trouble from rust or clogging is **entirely avoided.** Delivery of water into service pipes at any desired pressure **is guaranteed.**

Send for special leaflet and price list to the manufacturers.

INGLIS BOILERS

Built for all Services

Made in Canada

Built to Last

INGLIS BOILERS have been used in Canada for over half a century with unqualified success. Best of materials and best of workmanship are represented in their construction, and they give long, efficient and economical service.

We are also sole Canadian makers of Erie City Water Tube Boilers, Vertical and Horizontal.

Our representatives will be pleased to show installations of our different types of boilers to prospective customers.

POWER HOUSE

A monthly newspaper devoted to the Generation, Transmission and Application of Steam, Gas, Electric, Air and Water Power; and to the operation of Refrigerating Machinery.

Published by The MacLean Publishing Company, Limited, 143-153 University Ave., Toronto

MONTREAL: Southam Bldg. LONDON, ENG.: 88 Fleet St., E.C. WINNIPEG: 1207 Union Trust Bldg.

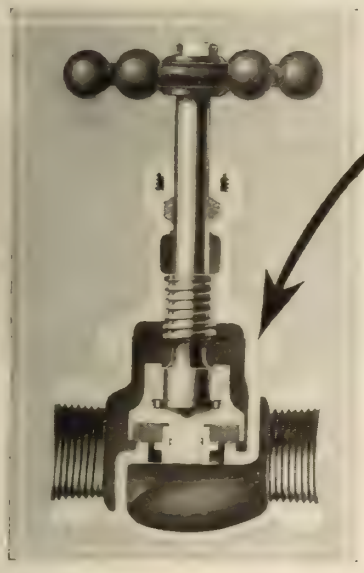
Vol XI—No. 3 Publication Office, Toronto—March, 1918 Published Monthly $1.00 per Year.

THE REASON WHY

TRADE PENBERTHY MARK **VALVES**

last longer and give so much **BETTER SATISFACTION** than other valves is due to their

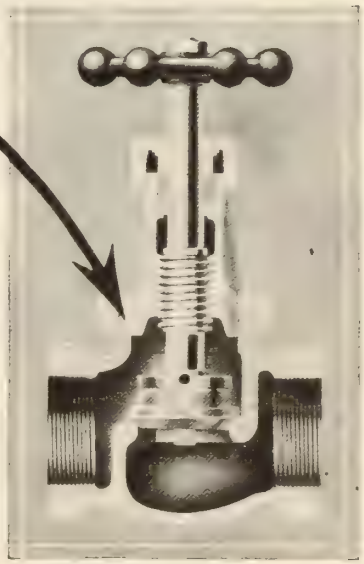
SUPERIOR CONSTRUCTION



ALL PENBERTHY VALVES HAVE THE EXTERNAL THREAD CONSTRUCTION

This Improved Construction Threads Outside of Body

(NOTE ARROWS ABOVE)



COMPODISK **REGRINDING**

Makes valve always accessible. Eliminates corrosion of threads. No corrosion prevents all strains in taking valve apart. Prevents spreading of body—causing a loose-fitting and unsafe bonnet. Makes a steam tight connection—no leaks. Permits of a more compact valve—consequently a stronger one.

PENBERTHY INJECTOR CO., Limited, Windsor, Ontario

Nationalized Service In Mechanical Rubber Goods

NEVER in the history of the mechanical rubber goods industry has the public ever enjoyed so great convenience as now in securing the widest possible range of mechanical goods of the highest known quality.

That this has been accomplished in the face of these trying and unusual business conditions is due to the splendidly efficient organization of this department of the United States Rubber Company.

Our factories are located in the big centers of the east and west. Branches have been established in all the most important cities. Agents have been appointed everywhere. By this development we have created the maximum ability to serve in manufacture and distribution of the most complete line of mechanical rubber goods ever brought together under one master mark.

This line includes such famous brands as Peerless Rainbow Belting, Rainbow Packing, Sawyer Canvas Belting, Eureka Fire Hose, Giant Steam Hose, Rinex Soles, Supremo Conveyor Belting, Holdtite Friction Tape, Peerless Honest John Packing, Relio Belting, Usco Radiator Hose, Rainbesto Packing, Buckeye Splicing Tape, Four Ace Seamless Belting, Paragon Fire Hose, Anaconda Tender Hose, Peerless Air Hose, Kold-Pak Jar Rubbers, Revero Garden Hose, Spring Step Heels, Giant Seamless Belting, Giant Suction Hose, Usudarian Packing; as well as hundreds of miscellaneous rubber items such as rubber soles and heels, rubber tiling, matting, mats, plumbers' supplies, rubber thread, rubber toys and golf balls.

That dealers and buyers may recognize in all future purchases that they are receiving the superfine product in mechanical rubber goods of "the largest rubber manufacturer in the world," these goods will retain their own famous brand names, and will also bear as master trade-mark — the great seal of the United States Rubber Company—a certain means of identification.

By this greatly improved representation we have nationalized mechanical rubber goods service in its broadest sense. By this increased capacity to serve, every factory, every branch, every agency becomes the actual presence, in each territory, of mechanical rubber goods headquarters.

By all means Be Sure You Get Good Babbitt Service

Good babbitt service plays an important part in industrial efficiency and economy. Thousands of horsepower are wasted every day in Canadian power houses by using inferior babbitts, when HOYT BABBITTS might just as well be used. There's no waste of power through friction in the plants where the Hoyt metals have been adopted—no fear of cutting, no over-heating of shafts. Wheels turn more smoothly and more economically with Hoyt's assistance.

There's over $5,000,000 worth of Hoyt Babbitts sold to the allied nations annually, an indication of its merits.

FROST KING Hoyt's famous general purpose babbitting metal has been introduced into the most particular power plants in the world, and is there to stay. Represents the accumulated experience of 40 years. A trial will prove its value in your plant. plant.

NICKEL GENUINE Gas and gasoline engines, marine engines and automobile engines run better with Nickel Genuine babbitting. If you once try it you will always use it. Why not put it to the test?

The Hoyt Catalog describes **Frost King** and **Nickel Genuine** and all our specific service babbitts thoroughly. Have us send it to you—contains valuable information.

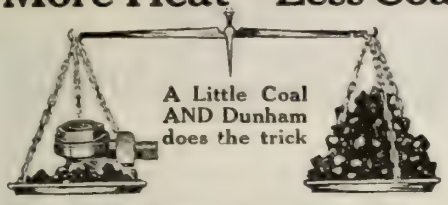
More Heat—Less Coal



The Dunham Radiator Trap —the Equalizer

Made Entirely of Brass and Bronze

The Dunham Radiator Trap is the foundation of The Dunham Heating Service. It occupies a position at the outlet side of each and every radiator. It automatically allows the air and water to escape and KEEPS IN THE PRECIOUS HEAT. Right here—at the point where, in ordinary heating systems, much coal is wasted—many buckets of coal are saved daily by Dunham Service users.

In these War times it is imperative that coal be saved wherever possible. Save coal! Save coal! Save coal! is the cry that is sounding all over the Country.

The DUNHAM HEATING SERVICE

What the Dunham Radiator Trap Means to *You*

Five to ten inches of vacuum WITHOUT USE OF JET WATER.

No broken vacuum because of LEAKY TRAPS.

Superior and sustained circulation, easily *maintained on low pressure* because air and water are eliminated.

MORE HEAT—LESS COAL—LESS LABOR.

Write us today.

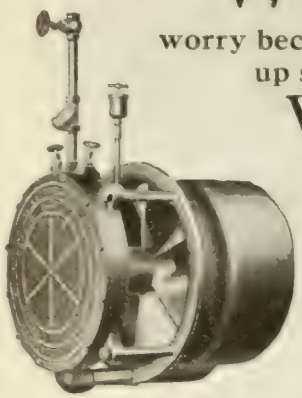
WHY

worry because you cannot keep up steam pressure

WHEN



it is so easy and cheap to overcome your difficulties by installing a

COPPUS TURBO BLOWER

It means constant steam pressure, regardless of uneven loads, poor draft and poor coal, and it will pay for itself in a short time on account of better combustion. It also will increase your boiler capacity to 200, and even 300%, of its normal rating without injury to the boiler. Cut out this Ad., put your name and address on the margin and mail to us. Without further trouble you will get all the particulars.

500,000 H.P.

In boilers equipped with Coppus Turbo Blowers in four years. The Coppus has replaced a great many other blowers, but no other blower has ever replaced a Coppus.

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compressors

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction.* Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under any unforeseen strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satisfactory operation, but practically *eliminates expensive shut-downs.* Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring oiled bearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

Speed up with Electric Power

C-G-E Motors and Control increase production and reduce maintenance.

Here are some of the ways in which modern industry has been speeded up by putting electric power to work in the right place.

Metal mines have boosted output to meet world-wide demands. All tonnage records have been smashed in the steel industry. Greater automobile output has lowered prices and given better road transportation. More and better cloth has been produced at lower power costs. Contractors find electric drive faster, more elastic and cheaper than any other for hoists, pumps, concrete mixers, cableways and other equipment.

On the left is shown the standard C.G.E. induction motor for general purposes. The C.G.E. mill type motor, on the right, is specially designed for the severe service of steel mills, but is equally applicable to crane, shovel, bridge and other heavy duty.

Any problem involving the use of power can be simplified by the application of electricity. The Canadian General Electric Company is well equipped to lend valuable assistance in working out such problems and is glad to co-operate with contractors, manufacturers and engineers in every possible way.

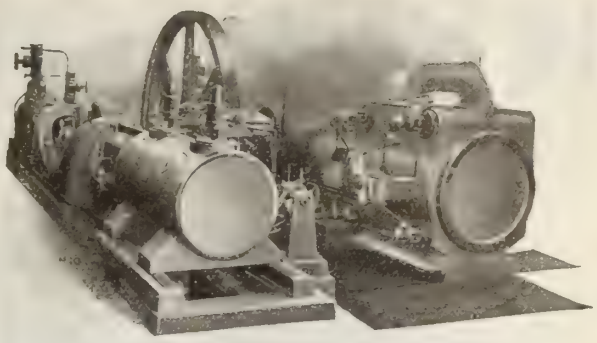
ECONOMIZE

The word that means most to American business to-day.

To Economize in the ice-making and refrigerating business means to

Save LABOR
Save FUEL
Save AMMONIA
Save REPAIR COSTS

These are the Cardinal Points by which Frick designers have guided the building



of FRICK MACHINES from their earliest beginning.

During nearly forty (40) years' experience this policy has proven itself a money saver for Frick users.

Frick Machines prove their worth. Ask us to show proof.

Frick Company
WAYNESBORO, PA. U.S.A.
ICE MACHINERY SUPERIOR SINCE 1882

Canadian Representatives:

FRICK ICE & REFRIGERATING COMPANY, MONTREAL, CANADA

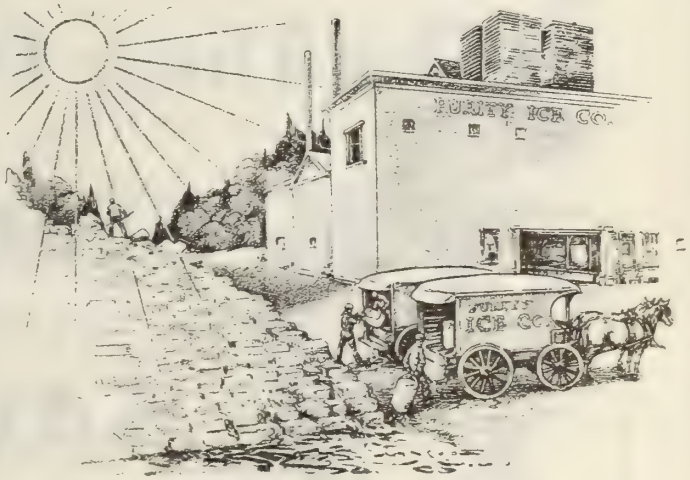
Would You Store Ice in the Sun?

—a foolish question, of course, but leaving brine or ammonia lines exposed to the heat of the atmosphere is just as illogical. The heat of the air readily passes through the conductive pipe metal, and a big loss of refrigeration results. Of course, all of this loss cannot be eliminated, but 80% of it can be saved by the use of

Nonpareil Cork Covering

For Brine, Ammonia and Ice Water Lines

Under average conditions, 330 tons of refrigeration, costing approximately $245.00, is the loss per year from only 200 feet of 2-inch bare, cold pipe. *If your brine or ammonia lines are uninsulated, you are losing in the same proportion.*



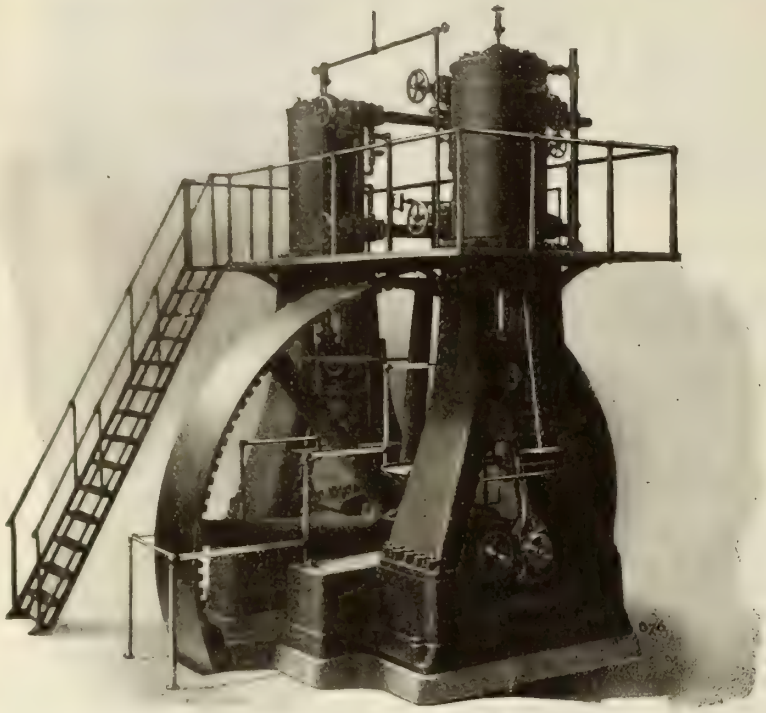
Nonpareil Cork Covering, composed of pure, compressed, granulated cork, bound together with the natural cork rosin, makes the most efficient type of cold pipe insulation yet devised; an excellent non-conductor, practically non-absorbent, trim and neat, and exceedingly durable in service.

Why not find out how much Nonpareil Cork Covering will save in your plant? Complete information and sample, on request.

ARMSTRONG CORK & INSULATION CO., 504 McGill Building, Montreal, Que.

Also manufacturers of Nonpareil Corkboard for cold storage rooms; Nonpareil Insulating Brick for boiler settings, etc.; Nonpareil High Pressure Covering for steam lines; Nonpareil Cork Machinery Isolation for deadening the noise of machinery; Circle A Cork Brick for cold storage room floors; and Linotile for office floors, residences, etc.

REFRIGERATION



Owing to the conditions imposed by the War, the use of Mechanical Refrigeration was never more of a necessity than now.

Our mission is to advise with prospective customers concerning their requirements and then to furnish a plant best suited to meet existing conditions.

There is a YORK Machine to meet every practical condition of MECHANICAL REFRIGERATION.

TORONTO MARCH, 1918

CONDITIONS AFTER THE WAR*

By LT.-COL. THOMAS CANTLEY
Chairman of the Board, Nova Scotia Steel and Coal Co.

ALTHOUGH the transition from war to peace conditions—whenever it may come—must cause some temporary difficulty and disorganization, there is a confident feeling that there will rapidly develop a huge demand for the products of the steel industry in order to make good the devastation of war, and also to cover the vast arrears of commercial work which have been so long held up.

There is the further fact that the world scarcity of food, the devastated farms, manufacturing plants, towns and homes of Europe will make for an enormous immigration to Canada, to accommodate which will cause the opening up of vast new agricultural areas, with a consequent demand for railways, bridges, buildings, tools and implements. The prosperity enjoyed by the agricultural population should also result in a very great demand for farming implements. Railway equipment and rolling stock in Canada, and in fact the shortage of railway equipment throughout the world, is great, while needed replacements are not being made, and there is a veritable famine for equipment of this character everywhere.

These facts seem to lead to the inevitable conclusion that while there may be a slight hiatus immediately following the war's end, within a very short time thereafter Canada will embark on an era of unexampled and unprecedented development and prosperity, while the iron and steel industry of the Dominion will be one of the first to participate.

May the day soon dawn when Canada's heroic sons, who have so gloriously battled for liberty and world freedom, will be triumphant and free to return to their homes and again take their place in their old-time peaceful pursuits, honored by all for what they dared and what they have done.

Notes on the Design and Testing of Air Lift Pumps

B. A. W. Purchas *

The air-lift pump has become one of the most economical methods of raising water, the simplicity of construction and the almost entire absence of moving parts giving reliability in operation and avoiding the necessity for skilled supervision. The design of these pumps being subject to more or less development the subject matter of the following article is of more than passing interest.

THE subject of air-lift pumping has not received the attention it deserves from engineers, and has fallen into disrepute with many. There are several good reasons for this, among which may be mentioned the lack of a satisfactory theory, the low efficiency of most installations, and the lack of complete and accurate reports of tests, so that the causes of the low efficiency are obscured.

An attempt is made in this paper to rectify the first, to show how the second can be improved, and to point out in what respects many reports of tests are lacking in information essential to a thorough analysis for checking theoretical formulae and deductions.

An account is given of several series of tests, with a description of the methods and the equipment. The theory of the pump is then reviewed, and a novel method of approaching the subject is given, from which it should be possible to evolve rational formulae for designing.

Equipment and Methods for Testing

General.—The wells on which these tests were made form part of a water supply system, of which an account was presented to the Institution of Civil Engineers some time ago. Series A of tests was given at that time, but further investigation showed that the author had wrongly calculated the actual volume of air used, and the average velocities of the rising mixtures in the eduction-pipe. By their kind permission, it is possible to reproduce these test figures with the errors corrected, and other valuable deductions added.

On pulling the eduction-pipes from the wells, after they had been in operation for some length of time, the interior surfaces were found to be heavily encrusted with nodules of rust, some ⅜-inch high, of such rugged outline as to leave no trace of smooth contour on the surface of the pipe. The tests of Series A are of one eduction-pipe when newly installed, and the tests of series B are of the same pipe when encrusted as described above. A comparison of these two series shows some very interesting points, Fig. 9. The eduction-pipe used in the tests of series C was badly encrusted, but that of series D was clean.

Air-Injection Foot-Pieces.—The foot-pieces used in the various tests are shown:—

For Series A in Fig. 1
For Series B in Fig. 1A
For Series C in Fig. 2 and 2A
For Series D in Fig. 3

The merits and faults of these are discussed later under the theory of the pump (page 13).

*Read before the Institute of Electrical Engineers, November, 1917.

Lift

In series A and B this was measured by lowering a float on the end of a steel-tape line between the eduction-pipe and the well-casing. The float was a piece of wood ¼ inch by 1 inch in section, and 6 feet long, weighted to float upright with about 5 feet submerged. This method, however, is not recommended, as the float will sometimes become wedged between the pipe-couplings.

In series C and D the lift was measured with the device shown in Fig. 4. This consists of a piece of heavy brass-pipe, inside which a small copper-float is free to slide at the least impulse. The whole is suspended by a duplex rubber-covered cable, graduated in feet, one wire of which is connected to the case, and the other terminating in a lump of solder on the lower side of the insulator, which forms the top of the case. At the top of the well an electric bell and batteries completed the installation. The case was lowered into the well, and its reaching the water surface was indicated by the bell at the ground surface ringing. By this means it is possible to measure the depth to the water surface within an inch. It is absolutely impossible to estimate correctly the lift from the gauge-pressure of the air at the well-head, and this should never be attempted. Some injection foot-pieces put from 5 to 10 lb. per square inch extra pressure on the air, and there sometimes is a loss of 5 lb. pressure due to friction in the air-pipe. A combination of these losses might make an error of 30 feet in the estimated lift. To estimate the lift from the air-pressure required to start the well flowing is equally impossible since, once the well is started, the lift nearly always increases. Reference to tests 1, 2 and 3 of series D, among others, shows that under certain conditions the air-pressure at the well-head may be less than that equivalent to the submersion head of the foot-piece. This may be accounted for by noting that a column 600 feet high of air under 135 lb. per square inch pressure will exert an additional pressure on the base of a column of 3.25 lb. per square inch, due to its weight.

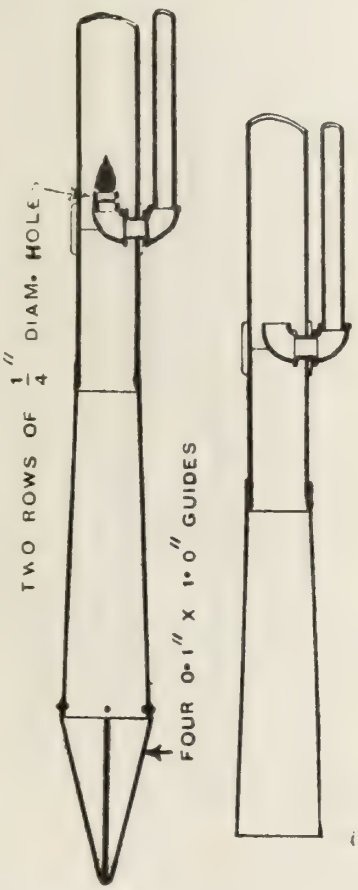

FIG. 1, SERIES A.

FIG. 1a, SERIES B.

An alternative method of measuring the lift is recorded by Mr. Kenneth Allen in a paper read before the Engineers' Club, of Baltimore (in 1908, on the wells at Atlantic City, U.S.A.

Air-Compressor and Measurements of Air Used

The air-compressor is a two-stage, with both air and steam cylinders compounded. The sizes of the more important parts are as follows:

	Inches
Diameter of the air-cylinders	10 and 18½
Diameter of the steam-cylinders....	12 and 22
Stroke of all pistons	18

The air is drawn through a combined forecooler and filter outside and on the shady side of the building, and passes through an intercooler between the two air-cylinders. The cooling water is circulated by a double-acting piston pump of 5½ inches bore, and 5 inches stroke, driven direct from the crank-shaft of the compressor. The suction valves of the low-pressure cylinder are semi-rotary, and are mechanically opened and closed by an eccentric on the main crank-shaft. All other air-valves are automatic, spring loaded and air-cushioned.

Many tests, which would otherwise be of the greatest value to the designer, are rendered of only doubtful value because the volume of air used was not carefully measured; hence the average velocities of the rising mixture can only be approximated. These velocities are the most important items affecting the efficiency of the pump, and those on which more than any other accurate data are required at the present time.

It is found in checking the published figures from too many tests that the volume of air used was calculated from the known displacement of the low-pres-

sure piston of an air-compressor allowing volumetric efficiencies of 95 per cent. and 97 per cent. Considering the types of compressors used, these figures are impossible, and are based on lineal measurements from indicator diagram on the assumption—unjustified by experiment—that the temperature at the beginning of compression is the same as that of the air at the intake.

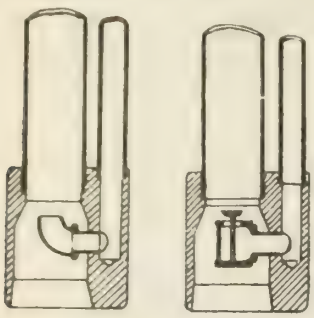

FIG. 2a. SERIES C. FIG. 2.

The true volumetric efficiency of a compressor based on the ratio of air drawn in at atmospheric pressure and temperature to the displacement of the low-pressure piston will vary:

For single-stage compressors, from..... 50-70%
For two-stage compressors, from..... 60-80%
For three or more stage compressors, from 80-95%

The above figures are taken at random from various sources, and it is impossible to state average values.

Returning to the tests here recorded, prior to each series the air-valves of the compressor were examined, and their seats put into good condition. On 25th and 26th April, 1914, tests were made of the volumetric efficiency of the compressor, and again on 7th and 8th May, at the end of each test of the air-lift pump. The discharge from the compressor was measured by means of an orifice, the form of which and the method of connexion to the air-receiver are shown in Fig. 5. This meter is a duplicate of that used by Professor R. J. Durley, of McGill University, Montreal, to determine the coefficients of the discharge or air through certain forms of orifice. An account of his work is to be found in the Transactions of the American Society of Mechanical Engineers, vol. 27.

The formula given in the above paper for calculating the flow through the orifice, is:

$$Q = 0.6207\ Cd^2 \sqrt{\frac{i}{T}},$$

in which—

Q is the weight of air passing through the orifice in pounds per second.

C is the coefficient determined by experiment.

d is the diameter of the orifice in inches.

i is the pressure inside the meter-box in inches of water.

T is the absolute temperature F. inside the meter-box.

This formula only applies to sea level, so as the plant at Oilfields is 700 feet above, the following formula was used to compute the discharge:

$$Q = 0.1632\ Cd^2 \sqrt{\frac{i}{T}}\ P^a$$

P^a is the absolute pressure in pounds per square inch of the air inside the meter-box. This equals the barometric pressure, plus 0.036 i.

For testing air-lift pumps, it is probably more convenient to install a meter in the air line between the compressor and the well. This is more expensive to install, but the volumetric efficiency of a compressor is a very variable quantity, which cannot otherwise be measured during the tests of the well-pump. Such a meter is shown in Fig. 6. The principle is identical with the foregoing, and the same coefficients of discharge

may be presumed to apply, if the velocity of approach and the head be maintained within the limits tested by Professor Durley. In this meter the discharge will be found by means of the formula:

$$Q = 0.1632\ Cd^2 \sqrt{\frac{i}{T}}\ p,$$

in which—

i is the difference of pressure on the two sides of the orifice, measured in inches of water.

p is the average of the absolute pressures of the air on the two sides of the orifice.

From the foregoing formulae, the volume of air is found by the formula:

$$W = \frac{p}{53.17\ t},$$

in which—

W is the weight in pounds per cubic foot.

p is the absolute pressure in pounds per square foot.

t is the absolute temperature F.

A third and similar method of measuring the volume of air is possible through the research of Professor William Watson and Mr. Herbert Schofield, who determined the coefficient of orifice placed in the suction-pipe of a compressor.

Quantity of Water Raised

The discharge-pipes of the wells at Oilfields rise about twenty feet above the ground, and discharge over the rims of small tanks, against curved hoods which deflect the water downwards. The pipes are bent to gradual curves, and the last few feet are inclined about 70 degrees to the vertical. Permanent derricks of a light California oil-well pattern are built over the wells, and were the discharge-tanks erected vertically over the wells, they would have to be removed each time the eduction-pipes were pulled. From these small tanks the water gravitates through 6-inch mains, laid along an overhead platform,

to two 84,000 gallon corrugated galvanized iron tanks and one wooden tank of like capacity. The iron tanks average 32 feet 9 inches in diameter, and 13 feet 4 inches in depth. The circumference of each ring of these tanks was carefully measured and checked, also the depth of the corrugations and the thickness of the plates. These measurements were taken when the tanks were full to the level at which the measurements were being taken, and from these figures a table of capacities was prepared for each eighth of an inch of depth.

Prior to each test, the well was pumped for sufficient time to allow all conditions to become constant, and the water meanwhile delivered into one tank. At the commencement of the test the water was diverted into another tank and switched back into the first again at the end of the test. All outlets from this measuring tank were closed and under observation at all times during the test.

Such facilities for measuring the quantity of water are rarely available, but there are several alternatives, such as weirs or Venturi tubes, which give equally accurate results. Many tests record only the combined performance of two or more wells; this is unfortunate both from the owner's point of view, and from that of engineers, as the information is too general; the extra cost of individual meters for each would undoubtedly be justified by showing some chance of improvement in the efficiency of one or more of the wells.

One writer who has contributed the results of some very instructive tests, measured the quantity of water pumped in a reservoir, the size of which unfortunately would only permit of runs of ten minutes' duration. It is the author's opinion that no test of an air-lift pump should be of less than one hour's duration, and that it is better to run this length of time and measure the water with some form of calibrated meter, than to run shorter tests and measure the water in any other way.

Indicated Horse-Power of Compressor-Air Cylinders

For this purpose an external spring Tabor indicator was used. This instrument had seen but little use, and was in perfect condition throughout. Great care was exercised throughout the tests to obtain true representations of what was taking place inside the cylinders. The revolutions of the compressor were recorded by an Ashcroft counter, and were controlled by a steam throttle-governor, which was operated by the variation of both the speed of the engine and the pressure of the air in the receiver.

Nature of the Discharge from the Wells

These observations were taken by two observers for three periods of five minutes each during each test. Where the discharge was 50 per cent. or more of the total cycle, the intervals were remarkably constant. The values here given are averages of times observed with an ordinary watch:

Series A.—These observations were recorded in the paper presented to the Institution of Civil Engineers, and are therefore not repeated.

Series B—

Test 1. Periods of discharge of thirty-five seconds' duration at intervals of one minute and twelve seconds.

Test 2.—Periods of discharge of forty-three seconds' duration, followed by a pause of five seconds, then a discharge of perhaps ten gallons, followed by a pause of thirty-three seconds before the cycle recommenced.

Test 3. A steady flow of emulsion ending in two short and violent ejections, the whole lasting thirty-three seconds. After a pause of five seconds, there would be a discharge of ten to twenty gallons, followed by a pause of twenty-eight seconds before the cycle recommenced.

Test 4. Periods of discharge of thirty-three seconds' duration at intervals of twenty-three seconds. During the interval there would be one fairly strong spurt lasting one second.

Test 5. Periods of discharge of one second at half-second intervals.

Tests 6, 7 and 8. Discharge similar to that of Test 5, but at higher velocities.

In all cases the discharge consisted of an emulsion of air and water, and not of alternate volumes of air and water, as Dr. Pohle claimed for his system.

Series C—

Test 1. Periods of discharge of forty-two seconds' duration at intervals of two minutes and seven seconds.

Test 2. Periods of discharge of thirty-six seconds' duration at intervals of fifty seconds.

Test 3. Periods of discharge of forty-one seconds' duration at intervals of twenty-six seconds.

Test 4. Periods of discharge of two to four seconds' duration at intervals of two to five seconds. Very irregular.

Test 5. Very similar to that of Test 4.

Test 6. Similar to Tests 4 and 5, but the intervals did not exceed half a second.

Tests 7 and 8. Very similar to Test 6.

Series D—

Test 1. Periods of discharge of forty seconds' duration at intervals of fifty-two seconds. During these intervals, however, there were five discharges of one to ten gallons each.

Test 2. Periods of discharge of five seconds' duration at intervals of five seconds.

Test 3. Periods of discharge from five to ten seconds' duration at intervals of five seconds.

Test 4. Periods of discharge of short duration, one beginning before the previous one had quite subsided. The velocity of discharge did not appear to be as high as in Tests 2 and 3.

Test 5. Similar in nature to that during Test 4, but at higher velocity.

Tests 6, 7 and 8. Practically continuous discharge of emulsion of small air bubbles and water.

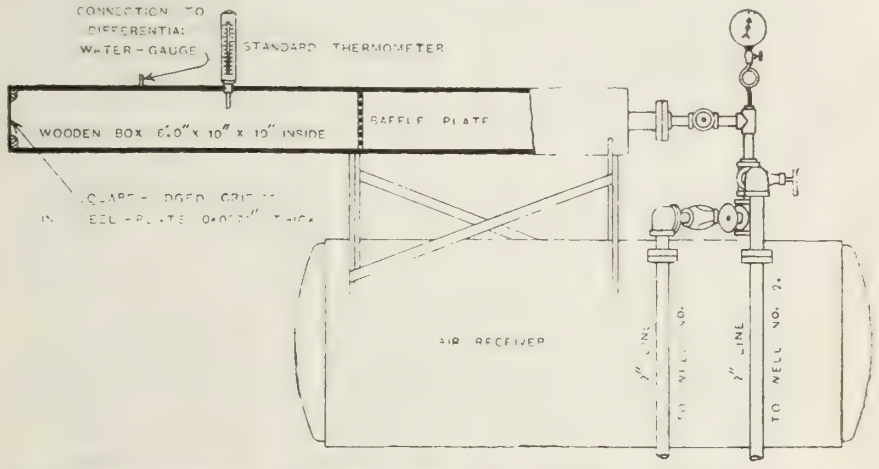

FIG. 5. ORIFICE METHOD FOR MEASURING THE VOLUMETRIC EFFICIENCY OF A LOCOMOTIVE AIR COMPRESSOR.

Method of Recording Observations

The comparison and analysis of published tests will be greatly simplified, if some standard form can be adopted. Most of the published tests lack certain important items, and other information, such as the submersion, is given in different ways, so that their analysis requires considerable work.

The author has adopted what he believes to be the most convenient form, and one which includes all details necessary to examine the behavior of the pump itself. The observations might, of course, be extended to include every part of the plant down to the fuel consumption, but such details can be foretold with fair accuracy by the manufacturers of the compressor. Since efficiencies of 80 per cent. seem possible with the air-lift pump in the near future it would not seem inopportune for some authoritative body to outline a method of making and recording tests of the air-lift pump, and its reverse the entanglement type of hydraulic air-compressor.

Probable Accuracy of the Tests at Oilfields

Lift.—This was measured within one foot equipment to 0.4 per cent., and did not vary more than 1.5 feet during any one test.

Quantity of Water Pumped.—The depth in the measuring tank was recorded by three independent readings to the nearest eighth of an inch, which is equivalent to:

8.7 cu. ft. in	2,652	or 0.33%	in Test 1 of Series	A
" "	1,284	" 0.68%	" "	B
" "	1,458	" 0.60%	" "	C
" "	2,340	" 0.37%	" "	D

Revolutions of the Air-Compressor.—The probable maximum error would be 5 in 7,750 in Test 8 of series D.

Volumetric Efficiency of Compressor.—The probable error in measuring the volume of air flowing through the orifice during the tests of series D is not more than 2 per cent., as the pressures and temperatures were all recorded within this margin. The values assumed for the tests of series A, B, and C, were based on the experiments made in April and May, 1914, taking into consideration the following :

(1) The speeds of the compressor.

(2) The known condition of the air-valves and guides.

(3) The volumetric efficiency shown on the indicator cards.

(4) The temperature of the air in the compressor suction pipe.

(5) The known condition of the scale in the cooling jackets, and the quantity of cooling water supplied. The cooling water was supplied by a piston pump driven direct from the compressor crank-shaft, in all cases.

It is difficult, therefore, to form a definite opinion of the probable accuracy of these latter values.

Indicated Horse-Power.—The maximum difference between the highest and the lowest "mean effective pressure" recorded during any one test, for the same end of a cylinder was 1.3 per cent. for the low-pressure cylinder, and 1.8 per cent. for the high-pressure. Considering the attention paid to details in the use of the indicator and the low speed of the compressor, the probable accuracy of the values given for the indicated horse-power is within 1 per cent.

Theory of the Air-Lift Pump

This subject is here treated in the following sequence:

(1) Design of air-injection foot-pieces.

(2) Nature of the rate of change of velocity of the mixture to the eduction-pipe.

(3) Operation of the pump as a whole.

(4) Submersion of the injection foot-piece.

Foot-Pieces.—The design of the foot-piece does not play such an important part in the ultimate efficiency of the pump, provided:

(1) That the fundamental laws of the losses in transmission of air and water are carefully kept in mind, when designing; and

(2) That the air is injected into the water in the form of small bubbles.

Any attempt to use the injector principle is pure waste of time, and generally leads to throttled air and water passages, and a back pressure on the air of two to five pounds per square inch, which represents so much wasted energy, for which no corresponding gain can be shown elsewhere. This throttling effect is very marked in the tests by Messrs. Brown and Behr, which were made with an inch diameter air-line terminating in a ⅝-inch diameter nozzle. Some of the tests by Messrs. Davis and Weidner show the same fault.

Fig. 1 shows the foot-piece used by the author in the tests of series A. Its obvious fault is the contracted water-passage, and its only excuse is its cheapness. The real reason that this was abandoned was the choking of the bottom of the air-pipe with rust and scale, so that eventually it caused an additional air-pressure of 30 lb. per square inch. Alternate exposure to warm air and water will corrode steel at an extraordinary fast rate. Before putting the eduction-pipe back into the well, after discovering this trouble, the "eddy cone" was removed, and series B of tests was made with the foot-piece shown in Fig. 1A. The foot-piece shown in Fig. 2 was originally used in Well No. 1, the aim being to inject the air in the form of small bubbles. This type suffered from the same faults as the previous ones. Series C of tests was made with the type shown in Fig. 2A.

When Well 2 was last re-tubed, it seemed probable that the eduction-pipe then inserted would be the largest ever required, and therefore full advantage was taken of previous experience and first cost was not so important. Fig. 3 shows the design of the resulting foot-piece, and this is the type used in series D of tests. The following points were aimed at in the design:

(1) To avoid loss of air-pressure in transmission from the well-head to the foot-piece, and keep the air-pipe outside the eduction-pipe without resorting to the use of the annular space around the outside of the eduction-pipe. An air-pipe run inside the eduction causes additional frictional losses in the rising mixture, with no corresponding gain elsewhere.

(2) To provide a pocket to catch such scale and rust as may form in the air-pipe, and thence fall into the foot-piece.

(3) To introduce the air into the water in the form of small bubbles, as it has been claimed that the velocity of slip of an air-bubble through water varies as the square root of its volume. Since designing this foot-piece the author has found that Mr. Joseph P. Frizell, member American Society of Civil Engineers, outlined the same type of foot-piece in 1880, and in "Engineering News" of 8th June, 1893, referring to the reverse process of compressing air by entanglement with falling water, wrote: "This method was suggested by observing the very moderate velocity with which bubbles of air rise in still water, the velocity varying with the size of the bubble, from nine inches per second or thereabouts for minute bubbles such as result from a slight agitation of the water, to as many feet per second in the case of great masses of air."

Mr. Kenneth Allen, describing the equipment and tests of the wells under his charge at Atlantic City, U.S.A., in a paper read before the Engineers' Club of Baltimore in 1908, also from his experience supports the same.

Mr. Edmund M. Ivens, on page 143 of his book, "Pumping by Compressed Air," writes: "The small openings mentioned divide the air bulk into small streams and thoroughly aerate the column. Considerable gain in economy over other systems is realized thereby, as may be seen by comparison of the curves and tables."

(4) To provide orifices for the air that would not corrode and choke up, as did those drilled in steel and used in the foot-piece shown in Fig. 1

(5) To so proportion the water passages that there should be no sudden change in the velocity of the rising column. The water-passage at the bottom is 6 inches in diameter. From this point upwards the passage gradually contracts, and the water therefore is gradually accelerated until it reaches the bronze taper-nipple. As the water rises through this, it is assumed that the air is uniformly admitted through the 120 ¼-inch holes, and that the velocity of the mixture is constant. Beyond this nipple the velocity of the mixture gradually increases until the size of the eduction-pipe is increased.

(6) To provide some form of guide on the lower end of the foot-piece as shown in Fig. 1, to prevent its catching in the joints of the well casing when being lowered into the well.

There is no necessity for the foot-piece to be as long as that shown, unless it is so built as to form an auxiliary air-reservoir at this point; a feature which has some advantages. It is equally possible to combine all the above points with the exception of No. 1 in a

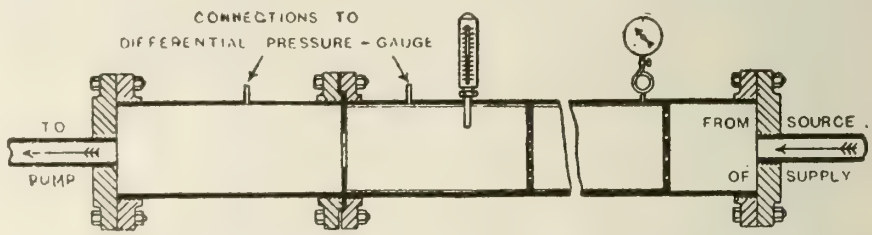

FIG. 6. HIGH-PRESSURE AIRMETER ORIFICE TYPE.

foot-piece to be used on an air-line inserted inside the eduction-pipe, and this latter construction is sometimes necessary if the well casing be small.

Velocity of the Rising Mixture

The air in the eduction-pipe expands as it rises, due to the diminished head of liquid above it, and it may safely be assumed that it does so isothermally on account of the large volume of water by which it is surrounded. In the case of a single bubble of air rising through water, the pressure on the bubble will vary directly as the head of water above it. In an air-lift pump in operation the air-bubbles are rising through a mixture of variable density, since the ratio by volume of air to water per foot length of eduction-pipe increases as the outlet is approached. Under these conditions the pressure in the eduction-pipe will vary as the ordinate to a hyperbolic curve, and the volume of each bubble as the ordinate to a straight line.

To find the volume of air passing any point in the eduction-pipe per unit of time:

Let P_1 be the absolute pressure of the atmosphere.

P_2 be the absolute pressure, equivalent to the head of submersion of the foot-piece.

V_1 be the volume of air delivered per second to the pump, measured at pressure P_1, and a temperature equal to that of the liquid being pumped.

x be the distance of the point under consideration above the point of air injection in feet.

L be the distance in feet from the point of air injection vertically to the outlet of the eduction-pipe.

The same weight of air, and likewise the same weight of water must pass each point of the eduction-pipe per unit of time; the volume of air flowing per second through the outlet of the pump is V_1 cubic feet, and the volume of air entering the eduction-pipe during the interval is $V_1\frac{P_1}{P_2}$. The increase of volume of the air in ascending the eduction-pipe is—

$$V_1\left(1-\frac{P_1}{P_2}\right),$$

and the total volume of air passing the point under consideration per unit of time is—

$$V_1\frac{P_1}{P_2}+\frac{x}{L}V_1\left(1-\frac{P_1}{P_2}\right).$$

The sum of the volume of air and water passing per second being thus found and cross-sectional area of the pipe being known, the average velocity can be calculated. This average of what is in some cases a widely varying quantity is the only value that can be calculated, and forms a very valuable deduction in analyzing the results of tests and in designing the pipe for a new installation. In cases where the air is injected in the form of small bubbles, and the pump is run at or over its most economical capacity, the velocity at any point appears to remain fairly uniform, and as has been pointed out above, these conditions should exist in a well-designed pump; therefore the average velocity calculated by the above method will be a close approximation to the true value.

FUELS OF CANADA

B. F. HAANEL, chief of the division of fuels and testing of the Dominion Department of Mines read a paper on "The Fuels of Canada" before the Canadian Society of Engineers, at Montreal on Jan. 22. Mr. Haanel prefaced his remarks by saying that Canadians were realizing that Canada was dependent on the American coal supply and was at the mercy of foreign strikes or industrial disorganization. Canada's supply of fuel might, therefore, be cut off at any moment. He continued:

"But there is even a more important factor which we must consider, namely, the necessity which may occur for the United States to keep her fuel within her own country. Such a situation may not arise for some time, but the indications are that we may have to meet such an emergency in the near future."

"Canada, to-day, is facing a fuel situation of great gravity, a situation which was not created by any special conditions in this country, but by those obtaining in the neighboring country. The United States is suffering from a shortage of fuels as a result of the withdrawal of skilled labor from the coal mines to other occupations, and, perhaps more directly, owing to the abnormal demand on the transportation facilities of that country for the carrying of material directly connected with the conduct of the war.

"We are not wholly dependent on the United States for our fuel supply, but we are dependent to the extent of 55 per cent. of our total coal requirements and 98½ per cent of our crude and refined oil products. Large and important sections of Canada, moreover, are almost wholly dependent on imported coal for house-heating purposes. This is a matter for grave reflections, since in a country such as ours, where artificial heat must be supplied during eight months of the year for the sole purpose of maintaining life, a continuous and dependable supply of fuel is absolutely essential.

"The present unsatisfactory—indeed alarming—situation can be improved only by a determined and energetic exploitation and utilization of our own vast fuel resources.

Canada's Needs

"The total fuel requirements of this country during the year 1916 amounted to nearly 30,000,000 tons of coal; 299,426,121 imperial gallons of crude and refined oil products, and firewood valued approximately at $60.000.000.

"Compared with her annual requirements, Canada's production of fuels for the same period amounted to 14,483,395 tons of bituminous coal, of which 2,135,359 tons were exported; 6,934,288 imperial gallons of crude oil and wood fuel to the value of $60,000,000. To meet our own needs, therefore, it was necessary to import 17,580.603 tons of coal, and 292,426,131 imperial gallons of crude and refined oil products.

"Of this quantity of oil, approximately 50,000,000 gallons were used on the railroads; 30,000,000 gallons for steamships, and the remainder 210,000,000 gallons, was used for lighting and heating, in the form of kerosene and, to a large extent, in the form of gasoline, for power purposes."

The principal fuel resources of Canada, Mr. Haanel said, were bituminous and anthracite coal, lignites and peat. The coals were in the extreme east and west, the lignites were in Alberta and Saskatchewan, and within the limits of these deposits were 12,000 square miles of peat bogs.

Bituminous coal as such was of use only in industries, but an excellent substitute for anthracite, for domestic use could be produced from bituminous coal by a process of carbonization at low temperature and briquetting, which was in actual operation to-day. Lignite and peat required preliminary treatment before becoming available for general fuel purposes. If this treatment was given them the fuel situation would be greatly improved.

Mr. Haanel was of opinion that, at comparatively small outlay of money it would be possible to establish a commercial plant to demonstrate that the lignites could be converted into a fuel entirely satisfactory for domestic and industrial purposes.

As for peat resources, the speaker said that an economic process for the manufacture of raw peat into an excellent fuel for domestic and to some extent industrial purposes was in use to-day, and had been employed for many years in European countries, notably Russia.

"Not until the utilization of a natural substance is forced by absolute necessity," he said, "will the most sincere and earnest efforts be put forth to successfully and economically convert it into a usable product. It appears to me that the time is at hand when necessity will decide that we Canadians utilize our peat resources, and in the most efficient manner. . . . We not only have the process for manufacturing peat fuel, but also sufficient detailed information concerning peat bogs of immediate importance to make a good start in the formation of a peat industry. . . . Seven bogs, conveniently situated with respect to Toronto, could supply that city with 26,500,000 tons of fuel, and seven bogs, within easy reach of Montreal, could supply 23.500.000 tons.

"The fuel situation in Canada, as I view it, is not a gloomy or a discouraging one, for we are endowed with fuel deposits on a magnificent scale. All that is necessary now is that proper exploitation and economic use be assured."

Electricity and Hydraulics

PRINCIPLES AND OPERATION OF MODERN ELECTRICAL EQUIPMENT—I.

By A. M. Pére.

ELECTRICITY plays a most important part, not only in modern civilization but in the very nature of this universe. To such an extent is this true, that scientists tell us that matter itself, formerly supposed to be entirely distinct and separate from energy, is in the ultimate composed of electricity.

In all walks of life a certain knowledge of the laws governing the supply and use of electricity is becoming more and more necessary every day, and to a man engaged in an occupation dealing with the production and utilization of power this knowledge is essential to his advancement.

A series of articles of which this is the first, will deal with the practical applications of electricity in the fields of industrial and power engineering, and is arranged to fill the needs of those who desire a knowledge of the principles underlying the operation of dynamo-electric machinery and auxiliary apparatus, and who at the same time wish to obtain instruction relating to the proper operation and care of such apparatus as they may have in their charge.

It is felt that, in many cases, text books and other sources of information

FIG. GENERATOR FOR BELTED SERVICE

deal with subjects removed from the sphere of the operating engineer and so contain information of little or no value to him. To meet this objection, as far as possible, all apparatus dealt with will be of standard types in everyday use and wherever feasible the questions of operation and the location of trouble and its remedy will be included.

A series of problems carefully selected and graded as to usefulness and difficulty will form part of the series. Certain of the articles will not admit of the giving of numerical problems and examples, in which case questions in the nature of a review involve a knowledge of the more important features of the article will be given in their stead. Problems will be worked out in detail in the issue following their presentation.

The Dynamo

Dynamos are divided into two general classes according to the character of the current they deliver. A direct current dynamo delivers a current that always flows in one direction; that is, the current never reverses although it may change in strength. Alternating current generators or alternators, on the other hand, deliver current that periodically reverses its direction of flow, the number of reversals per second, or the frequency, depending on the speed of rotation.

The modern direct current dynamo, while appearing in many forms and special designs, has comparatively few fundamental parts upon which it depends for its operation, the magnetic circuit, the armature conductors, the commutator and its collecting devices.

In order to gain an idea of dynamo design and operation and to familiarize the reader with its parts a commercial type of dynamo is illustrated, Fig. 1, and the remainder of this first article will be devoted to a description of its parts and a preliminary study of their relations.

The Magnetic Circuit

The magnetic circuit of a direct current dynamo consists of the field magnets with their exciting coils and the armature core. The field magnet is formed of a suitable frame made in various shapes depending upon the design of the machine and has two or a greater even number of pole-pieces partially engaging the armature circumference. On each pole of the frame is a magnetizing coil. Fig. 2 shows a four-pole field magnet and the relations of these various parts will be made clear by reference to the illustration.

The armature core also shown in Fig. 2 is built up of numerous laminations of sheel steel varnished and assembled on the shaft. As shown this armature core is slotted for the armature conductors. This type of core is standard for the larger designs of generators and motors, but some of the older types of machines made in the smaller capacities have a smooth iron core over which the coils have been wound.

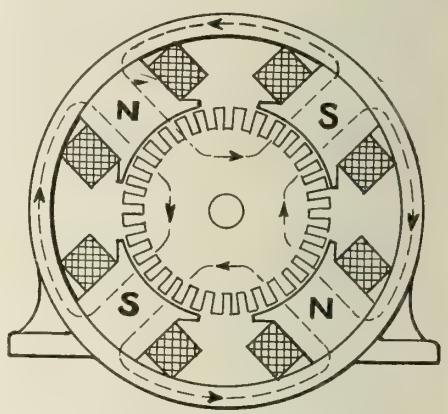

FIG. 2. FOUR POLE FIELD MAGNET WITH ARMATURE CORE IN POSITION

There are four materials which are commonly used in the construction of the magnetic circuit of a dynamo or motor; cast iron, wrought iron, sheet steel and cast steel. Efficiency, cost, weight and regulation determine the choice of material for any one machine. While cast iron is the cheapest material used for the construction of field-magnets its comparatively poor magnetic properties render it necessary to use a larger quantity of it than would be necessary say of wrought iron or steel.

An increase in the amount and cost of copper also results from its use owing to the greater length required. Steel is one of the best materials to use as regards its electrical properties.

The Armature

The revolving part of the direct current dynamo is called the armature, and it consists essentially of a number of copper wires or conductors joined together and grouped in a particular way, for the generation and circulation of the currents produced, these wires or conductors being placed in the slots of the core mentioned above, and held in place by binding wires or wedging devices.

The core is keyed firmly on the armature shaft and when the armature is revolved the conductors are whirled around at a high speed. Since the revolving armature occupies a central position and is surrounded by the poles of the field magnet, the conductors cut the magnetic lines of force, which are generated by

the field magnet and forced by it through the air gap and iron core of the armature.

This cutting of the magnetic lines of force, as will be explained later, gives

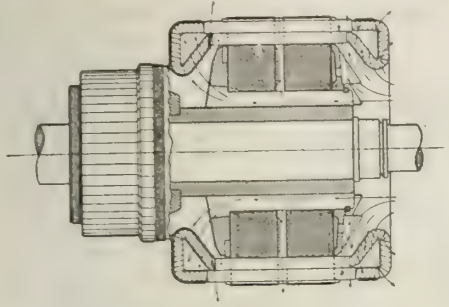

FIG. 3. SECTION THROUGH ARMATURE SHOWING CONSTRUCTION AND ARRANGEMENT FOR VENTILATING.

rise to electro-motive forces which tend to drive currents along the copper conductors and so, if the revolving conductors are connected in a circuit, currents will be generated.

Commutator and Brushes

Since these currents are generated in the revolving conductors it becomes necessary to employ some kind of a collecting device. On direct current dynamos and motors this portion of the machine is called a commutator. In addition to the collection of the generated currents the commutator in a manner explained later also serves to transform the alternating current generated in the armature into a continuous or one-direction current.

The poles of the field magnet are of two kinds or polarities, north poles and south poles arranged alternately. Since the revolving conductors on the armature are moved first past a north pole, then past a south pole, then past another north pole and so on in continual succession it follows that the potential created in the armature conductors will tend to cause a current to flow in first one direction and then in the other.

On inspection a commutator will be found to be built up of numerous strips

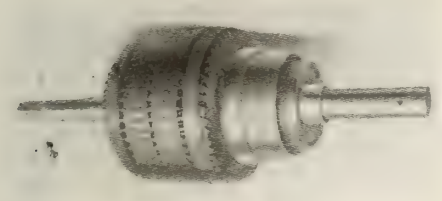

FIG. 4. ARMATURE COMPLETE ON SHAFT.

or bars of copper separated by narrow strips of mica. The copper used in the better class of machines is usually rolled or drawn so as to make it as hard and uniform as possible, thus eliminating all soft bars.

The mica used for insulation is usually a built up product consisting of flakes of natural mica, mixed with a binding material and combined into a solid mass by the aid of heat and pressure. This results in a uniform product of even thickness.

These bars are shaped with dovetail corners on their under side so that they can be securely clamped between end-cheeks and mounted on a shell or hub that is secured on the armature shaft. Insulating collars of built up mica are interposed between the bars and the clamping cheeks of the shell, so that each individual bar is electrically insulated from contact with a neighboring bar and with the shaft and other metallic parts of the armature.

At the end of each bar is formed a projection or riser by means of which the bar is connected to the armature windings. Thus if the commutator has 111 bars, there will be 111 risers connected to the windings at 111 equidistant points.

Brushes and Brush Gear

The name brushes is given to the stationary contact pieces which collect the current from the commutator, because in the early machines they were made of bundles or brushes of springy brass

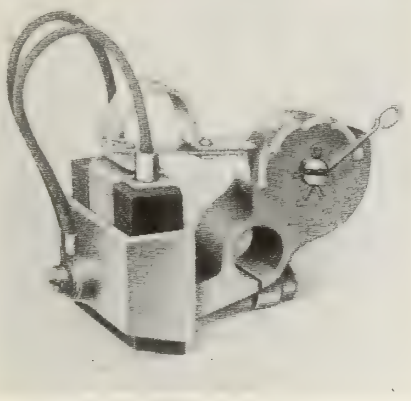

FIG. 5. TYPICAL BRUSHOLDER SHOWING MEANS FOR ADJUSTING BRUSH PRESSURE

wire. In present day practice they are frequently made of copper gauze or copper strips clamped in suitable brush-holders or more often of blocks of fine carbon held in holders with springs which press the carbon blocks with a springy pressure upon the surface of the revolving commutator.

In order to adjust the brushes to the proper position to collect the current without sparking they are fixed to a suitable frame or rocker which is itself supported on the bearing or to some other part of the machine frame.

This Month's Problems

Name the three most important features of direct-current generator construction.

What parts of the generator comprise the magnetic circuit?

What materials are used in the construction of the magnetic circuit?

Of what materials is the commutator made?

What three materials are used in the making of brushes for collecting the current?

READERS' QUERIES

Question.—Why does the negative pole of an electrical polarity indicator turn red while in circuit?

Lockport, N.S. Jno. Lousby.

Answer.—This action depends on the electrolysis of the solution contained in the tube forming the indicator. A solution of some salt of one of the alkaline metals is placed in the container together with the proper amount of some substance which will indicate the presence of an alkaline or basic substance. Phenolphthaleine is a substance which has the property of turning red in the presence of a base such as sodium in hydroxide or caustic soda.

In the case of a salt such as sodium sulphate the result of passing a current through the solution is the formation at the negative pole or kathode of a solution of sodium hydroxide or caustic soda, and at the positive pole of a solution of sulphuric acid. The solution of caustic soda momentarily existing at the negative pole causes the indicator or the phenolphthaleine to turn red. On the interruption of the current the sodium hydroxide and the sulphuric acid reunite and thus restire the neutral character of the solution and in consequence the red color disappears.

The above substances are merely given as an illustration of the principle upon which an indicator works and are not necessarily those actually employed in the commercial article.

Question.—I would like to obtain full information regarding the construction of an efficient storage battery large enough for lighting and with some power to spare for a medium small farm home. The voltage to be about 8 to 9 volts.—A. C. Holts.

Answer.—The making of lead storage batteries while simple enough as an experimental task is quite difficult and expensive for the amateur when the making of one large enough for house lighting is attempted, and it is recommended that the complete outfit be purchased from some reliable manufacturer. By doing this you would receive better satisfaction from the equipment as a whole and would be buying it much cheaper than the individual parts could be purchased.

The lead storage battery in the charged state consists of a positive plate of lead peroxide and a negative plate of finely divided lead, both dipping into sulphuric and of about 1.2 specific gravity. When discharged the surface of both plates has been changed to lead sulphate. The plates are brought back to the charged condition by sending a current through the battery in the reverse direction

* * *

Question.—Would you be so kind as to give me a simple rule for calculating the torque of motors?

Answer.—Multiply the E.M.F. in volts by the current in amperes and this pro-

duct by seven. Divide the product so obtained by the R.P.M. and the quotient will be the force exerted at a radius of one foot from the center of the shaft.

Turning moment in ft. lbs. $= 7W \div$ R.P.M.

The above approximate formula applies to any motor with the precaution that in calculating the torque for alternating current machines the true value for the watts as read on a wattmeter.

Question.—I would like to know if two single phase transformers would carry their full rated load when connected, open delta on a three phase circuit?

Answer.—On account of the fact that there is a thirty degree displacement between the voltage and current in transformers connected open delta and carrying a load of unity power factor, the capacity of the transformers is only 0.866 times their rated capacity.

Hence two-500 K.V.A. transformers connected in open delta on a three phase circuit will only carry 866 K.V.A..

Question.—In what manner is the speed of an alternating current motor calculated, the frequency and the number of poles having been given?

Answer.—It is current practice to base the speed of an induction motor on an allowance of 4 per cent. slip. In which case the following formula is used

$$\text{R.P.M.} = \frac{\text{Cycles} \times 60 \times 96}{(\text{Poles} \div 2)\ 100}$$

INDUSTRIAL PLANT FURNISHES STREET RAILWAY POWER

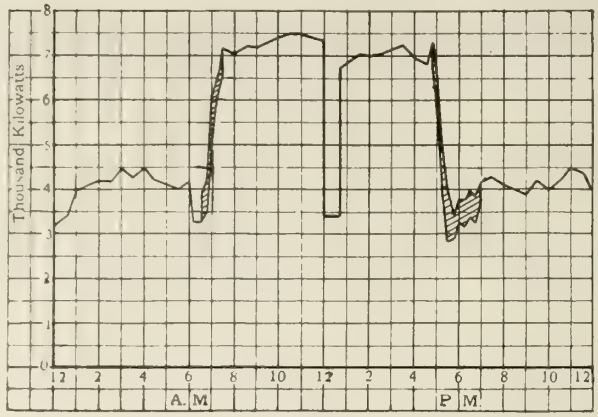
OBTAINING a high load factor is one of the problems to which the operating engineer of an industrial power plant gives practically no attention. Usually he can do nothing with the problem because the amount of the load and the time at which it is required is entirely out of his control.

Since his plant serves but one industry there is no opportunity for him to secure the diversity of use which is the salvation of the central station. However, it is often possible by looking around to find outside uses which will extend the period of peak load without increasing its magnitude, and at the same time materially benefit the new power user.

An interesting example of this is the supply of direct current by the Westinghouse Electric and Manufacturing Company to the Pittsburgh Railways Company for the operation of their cars in and about East Pittsburgh, Pa. Due to the tremendous increase in employees at the Westinghouse plant, the present overhead equipment of the street railway was overtaxed for about two hours morning and evening.

Since the railway company's generating plant was also heavily loaded at these times, it was considered better to buy current from an existing plant rather than erect a railway substation or string additional copper in feeders. Accordingly connections were made between the railway feeder system and the Westinghouse Company's rotary converter capacity in its power house and arrangements were provided to supply direct current at 500, 550, 600 or 650 volts according to the railway need.

As will be seen from the daily load



DAILY LOAD CURVE. SHADED PORTION INDICATES POWER DRAWN BY RAILWAY COMPANY.

curve the amount of the day's demand was not increased but its duration was somewhat lengthened, the shaded area indicating the power furnished by the manufacturing company.

As will be seen from the map, Figure 2, street railway transportation to East Pittsburgh is furnished over but three lines north-west and one line east. On this account the traffic congestion is very great at morning and evening. With the old conditions there were often annoying or even serious delays due to

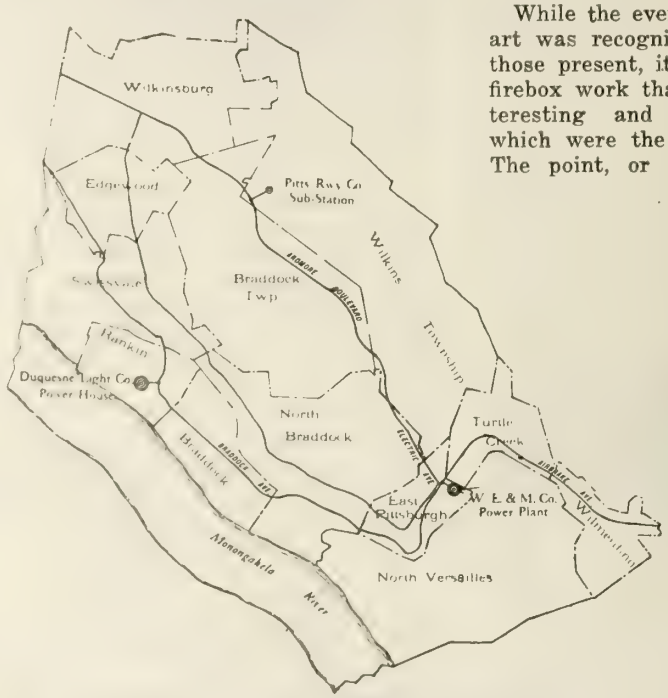


FIG. 1. VICINITY OF EAST PITTSBURG, SHOWING TROLLEY LINES SERVING THE DISTRICT.

power shortage. Since this new arrangement has been in operation, however, there has always been plenty of power to move cars at any time.

There are no doubt many industrial companies similarly located with respect to transit lines extending out a considerable distance beyond the last substation which could use such a method with great advantage. While the revenue from the sale of power is of course desirable the principal benefit will be found to be in the getting of employees to and from work on time in which an ample supply of power is a very important factor.

WELDING OF LOCOMOTIVE FIRE BOXES

THE importance of ovy-acetylene and electric welding in relation to the iron and steel industry was amply demonstrated at the December meeting of the Canadian Railway Club in Montreal, when the subject of the evening was a paper on "Oxy-Acetylene and Electric Welding and Cutting Processes in Locomotive Works." The subject matter of this paper (a reprint of which appeared in a recent issue of this publication) dealt largely with the application of these two processes as practised at the Point St. Charles shops of the Grand Trunk Railroad. While the paper in itself was of a highly interesting character, it was the discussion that followed which impressed all present with the rapid development and growing importance of this method of construction and repair in relation to locomotive and marine activity.

While the ever widening scope of this art was recognized and appreciated by those present, it was its adaptability to firebox work that brought forth the interesting and instructive arguments which were the features of the debate. The point, or points, upon which the discussion revolved were the debatable questions of the advantages and disadvantages of lap and butt welding when used in places where these joints would be exposed to the excessive heat of the fire on the one side and subjected to the high steam or water pressure on the other. From the statement of Mr. Dyer it is interesting to note that the Stratford shops use the oxy-acetylene process, while the electric process is the one adopted at the Montreal shops; the method in either case for general purposes being the butt welded joint. Apparently, considerable success has been attained from the butt welding process, as gathered from the experience of the Grand Trunk officials.

Prefers Lap to Butt

In direct contrast to this, however, Mr. Barry, of the St. Lawrence Welding Company, stated, that after a lengthy period of practical experience in the handling of firebox work, of a wide and varied character, it was his firm opinion that, irrespective of the process used, the lap weld was to be preferred over that of the butt weld. He also stated, however, that a satisfactory job might be accomplished by either methods, according to the skill and ability of the operator; but that this was a factor so uncertain that no guarantee could be given, even by the most experienced operator, that the weld was "perfectly sound."

He cited an instance where a tank head had been welded by the oxy-acetylene process by means of the butt method and had stood a test of 50 per cent. over the working pressure without the least sign of a "weep." Nevertheless, after being three weeks in service the head suddenly blew out, and upon examination it was found that, while the external appearance was in every respect perfect, the weld had not been made through the entire thickness of the plate. The head had come away so suddenly that no previous warning was given, but fortunately no one was hurt. Mr. Barry contended that had this been a lap joint, with the pressure tending to keep the surface in contact, that the head could not have come away before first giving some warning. He said "The factor of safety is something that cannot be overlooked. The question of safety is much more important than a firebox going out of service."

Apart from the advisability of using either method of weld, the problem of the man operating the blow pipe is probably the all-essential factor in the successful accomplishment of oxy-acetylene welding; the same also applying to the manipulation of the arc in the electric process. In speaking on the ability of the operator to do efficient work, Mr. Royer of the Welding and Supplies Company said, "One of the principal drawbacks in connection with the process of oxy-acetylene welding is the long time it takes to educate men to weld properly. A poor operator is liable to either stick the added metal to the plate or to burn the metal, and it takes time for the men to properly handle the blowpipe so as to neither get adhesion or burning, and to judge the correct temperature when to start the weld."

Need of Trained Men

A common fault of the beginner is to keep the flame of the blowpipe playing too long in one particular spot, thus localizing the heat and preventing the proper fusing of the adjoining metal, with the additional possibility of burning the steel or other material. The flame of the blowpipe should be kept continually moving with a slight elliptical motion, so as to distribute the heat evenly at the portion being welded. Speaking further, Mr. Royer said, "There is no doubt that a considerable amount of boiler work can be done very satisfactorily, if the men are properly trained, however, discrimination should be exercised in boiler work, in using only reliable welders on jobs where failure would be dangerous, and apprentices and beginners can be used on those parts where failure will not produce accidents. If a shop could get efficient welders, it would save thousands of dollars in maintenance costs."

Mr. Buckland of the C.P.R., speaking on the effectiveness of the weld in relation to the ability of the operator, said "A blacksmith will not take a piece of metal and try to weld the tip of it to the tip of another piece. He wants the metal properly heated to produce a successful weld. I think we should pay more attention to selecting good men for this class of work. If you are making a weld in a firebox on a long narrow strip, you localize the heat along that weld and it cools rapidily, and there must be an initial strain on that weld, which should, to my mind, be removed by slight annealing after the weld has been made." This brought out the fact that in the repairing of marine boilers in Europe, the practice of hammering the weld with a small hammer, immediately after the weld had been made and while the metal was still red hot, was extensively adopted. This was intended to take the place of the rolling process to which the plate was originally subjected. Following this hammering process the entire welded portion and its surrounding parts are annealed by bringing it and the adjoining sections to a cherry red by means of the blowpipe. By this method it has been claimed that the strength of the joint would be increased from 85 to 95 per cent. of the strength of the plate.

Clean Metal Essential

One of the objectionable features in reference to lap welding, as emphasized by Mr. Buckland, was the extreme possibility of the presence of scale on the sheet, which if not previously removed would undoubtedly result in a very poor weld. To overcome this it would be necessary to take off all the scale and see that the sheets are properly prepared.

In answer to a question from one of the members in connection with the improvements that had been made in getting away from the double thickness of metal, on or adjoining the fire line, Mr. Barry said, "We do not put patches in fireboxes that come in line with the fire. Anyone who does that should not be allowed to use the boiler. The reason is that the fire causes such an amount of expansion and contraction that the weld cannot last. You have to get above the fire line a foot or more, and the higher you get above the fire line the better the patch will hold. Any weld alongside of the fire line is going to burst sooner or later—generally sooner."

Educational Research Needed

With the process of oxy-acetylene and electric welding occupying such an important position in the metal working industries it would appear that the time is opportune for the formation of some form of research bureau to thoroughly study the many questions that are involved in this comparatively new but rapidly developing science, with the purpose of putting the practice on a more certain basis regarding the efficiency of the work and the education of the men that are necessary for the production of reliable and satisfactory work. At present the art is greatly curtailed owing to the lack of knowledge on the part of the majority of operators regarding the fundamental principles pertaining to the technical characteristics of the processes. It would also appear that for men to become thoroughly efficient at this work they must acquire considerable knowledge pertaining to the physical nature of the different metals upon which they are required to make welds. The chemical reaction that must necessarily accompany the fusing of the two metals and the addition of the filling rod must change the nature of the weld from that of the metal in the body of the plate or object being welded, and it is this change that eliminates the possibility of placing a known factor of safety on this particular class of work.

A NOVEL SCHEME FOR WRECKING OLD MASONRY

THE expansive force of quicklime has lately been used in breaking up brick masonry. It was necessary to remove three foundation piers, each 12 ft. by 20 ft. in area, and 12 ft. high, and similar piers supporting working engines on each side prevented blasting. Cutting and breaking up by hand being too slow and expensive, the new method was tried. Vertical holes three inches in diameter and three feet deep were drilled three feet apart in both directions, and were filled to within six inches of the top with quicklime, fresh and well slaked. Water was poured in and the holes were closed with brick dust, well tamped. Cracks started in ten minutes and soon broke the pier top into three foot cubes, making subsequent hand operations easy.

STREET VACUUM CLEANER

A vacuum street cleaner has been purchased for use on streets in the Panama Canal zone and was placed at work this week. It is a motor propelled vehicle carrying a sheet steel bin divided into two compartments. A large blower is driven by a 18 horsepower gasoline motor, and by this means dust and dirt are lifted from the street just as a vacuum cleaner for house use does its work. Stiff brushes mounted in front of the suction-head stir up the dirt so that it may easily be lifted by the suction. The cleaner covers 12½ feet at each operation, and runs at from three to five miles an hour. It operates on dry streets, does away with the cost of sprinkling, and saves in labor cost, as it cleans about 200,000 square yards in eight hours, and is operated by one man, the chauffeur.

Steam and Its Generation

MODERN CONDENSER PRACTICE*

By D. D. Pendleton

FOR high duty work, 28-inch vacuum or better, the type of condenser to be selected should be thoroughly studied, taking into consideration the engineering, physical and commercial conditions. The question of water is of prime importance and should be studied as to : Quantity, kind, clean, dirty, acid, etc.; pumping head; source, natural or artificial; average temperature. With these points settled, the commercial vacuum which is practical to maintain may be determined, always bearing in mind that the average log of a properly designed, rated and operated surface condenser will show better vacuum than a jet machine and in turn better than a barometer machine, due principally to the conditions as to air leaks and exhaust piping losses.

Surface Condensers

The surface machine also allows the condensate to be reclaimed as pure, distilled water for boiler feed, thus requiring only a moderate amount of make-up water to be treated in cases of unsuitable boiler feed supply. There is no limit to the size of surface equipments—they are now being made in sizes from 100 square feet up to 70,000 square feet.

The barometric condenser is limited in size by the expensive exhaust piping. The low level jet is also limited as to size. This is due to the removal or tail pump and air pump limitations and to the power necessary for driving the pumps. Units of 7,500 to 10,000 kilowatts seem to be the practical limit for these pumps, although there have been installed in certain cases twin jets of 20,000 kilowatts capacity.

A 20,000 kilowatt turbine consuming 12½ pounds per kilowatt hour or a total of 250,000 of steam would require for surface work 31,250 gallons of water per minute at 15-degrees difference, with 70-degree water and 28-inch vacuum, against a 10-foot head. This would require approximately 100 horse-power, the air and condensate pump of the hydraulic type requiring 140 horsepower additional or a total of 240 horsepower with one set of auxiliaries.

The jet at a 5-degree difference would require 20,000 gallons per minute against a 40-foot head if no booster pump were required, or approximately 400 horsepower. The pump would require about 250 horsepower more, making a total of [illegible]

Conditions Influencing Choice

After considering the local conditions, the choice of a condenser should be made upon the power requirements of operating cost, always considering the points mentioned in the preceding paragraph. Assuming a case of 40,000 pounds of steam per hour, 28-inch vacuum with 70-degree water, the power requirements are as follows: Surface condensers at 15 degree difference would require 5,000 gallons per minute. Since the discharge should be sealed, a working head of 10 feet should be ample, under ordinary circumstances, requiring a water horsepower of 12½. At an efficiency of 75 per cent. on the centrifugal pump, a pumping horsepower of 16 2/3 would be required. Using the wet and dry system the air pump would require approximately six horsepower, the condensate pump about 2½ horsepower, making a total of approximately 25 horsepower. The low type jet owing to the low efficiency of the removal pump would require more power.

At a temperature difference of 5 degrees, however, less water, or 3,100 gallons per minute would be required. A head of 36 feet being the discharge head from the condenser, plus friction would make approximately 27.9 water horsepower. The efficiency of the removal pump being about only 50 per cent, it would require a total of 55.8 horsepower. The air pump, however, would be approximately twice as large as for the surface condenser and would require 12 horse power, giving a total of 68 horsepower for the jet system. The barometric type would require same amount of water, but the water must be lifted to the condenser head using the total static head plus suction and lift on the pump, less the suction effect of vacuum. This usually can be considered a net head of say 40 feet, making a total of 31 water horsepower; and at an efficiency of say 70 per cent. on the supply pump, a total of 44½ horsepower would be required.

The same air pump would be used as in the case of the jet, requiring 12 horsepower, making a total of 56½ horsepower. The hydraulic or other types of air pumps and the steam jet would materially increase the air removal power requirements.

Summing the case up we have: Surface, 25 horsepower; barometric, 65½ horsepower—an increase over the surface of 126 per cent. low type jet, 68 horsepower plus an increase over the surface of 172 per cent. The relative costs would be: One hundred per cent. for the low type jet; 100 per cent. for barometric, not including the exhaust piping; and about 200 per cent. for surface equipment.

The rating of the surface of a condenser depends principally upon the amount of heat that can be dissipated by each square foot of surface, this being determined by the heat transfer per degree difference between the mean circulating water temerature and the tempperature of the vacuum to be attempted.

Condenser Tubes

The tubes in surface condensers have been a source of much thought and experiment. The material used should be pure electrolytic copper, high grade spelter, having not over 0.07 per cent. lead, 0.03 per cent. iron and .05 per cent. cadmium, and pure tin. No scrap should be used. The most common mixtures are: Pure copper, muntz metal (60 per cent. copper, 40 per cent. zinc); admiralty (70 per cent copper, 29 per cent. zinc and 1 per cent. tin). The standard tubes usually are No. 16 or 18 B. w. g. in thickness and ⅝ inch, ¾ or 1 inch outside diameter, depending upon conditions.

The quality of water available and the temperature usually determine the vacuum which is practical to maintain. This quantity can be varied for the same vacuum by varying the assumed terminal temperature difference, which will directly vary the surface for any given rate of heat transfer. A terminal temperature difference of 5, 10, 15, or 20 degrees can be used. A ratio of heat transfer from 300 to 500 may be employed. For standard commercial work, a terminal temperature difference of 15 degrees is usually conceded the best practice and a heat transfer of 300 to 350 is conceded the most conservative.

Water Velocities

Eminently good engineers have advocated water velocities for surface condensers as high as 10 feet per second, stating emphatically that 8 feet is conceded practical and standard. From tests of large condensers, a water velocity of 4.7 feet per second seems to be the average; for the purpose of discussion, say 5 feet. Now suppose that this velocity be increased to 8 or 10 feet; the power requirements for such conditions would be excessive. All talk of 8 to 10 feet per second seems to be absurd, in view of the fact that there are very

few commercial and practical plants operating under such conditions.

Water quantities are usually figured at a 5-degree terminal difference as standard practice, although results have easily been maintained at the vacuum temperature or a 100-per cent. water efficiency.

The removal or tail pump, as already stated, requires the larger amount of power—usually on river conditions the water has to be supplied to a cold well by a booster pump, drawn into the condenser by suction and expelled against the vacuum plus any friction and outside static head. The booster pump power has not been considered in the example of power requirements for the types already given.

Air Pump Requirements

The air pump is required to remove air coming in with the water as well as air entering through leaks in the exhaust or other piping and air entering with the steam. Here also the water quantities are figured as in the low type jet machines. The water supply can be more easily figured for it can be pumped directly to the barometric head without booster or auxiliary pumps. The air pump requirements are the same as in the low type jet.

After fixing the type of condenser to be used, the next step should be a study of the auxiliaries for equipment. These can be divided into two kinds: Motor driven and steam turbine or steam engine driven. It is very easy to analyze the power requirements of the motor-driven air, circulating and hotwell pumps for the electrical energy is taken directly from the switchboard. Steam turbine or engine drives, however, bring up the question of the return of heat to the feed water or heat balance and this so often complicates matters that we lose sight of the true power consumed. Roughly, 90 per cent. of the steam of the auxiliaries will be returned as heat to the feed water provided there is enough water of a suitable temperature to absorb this heat. The amount of feed water available for absorbing this heat varies with the load on the main unit. The result is that at times of light load there is a grave danger of showing an excess of exhaust steam. This militates against the use of steam-driven auxiliaries to some extent and had led to the development of combined drives using turbines and motors.

In the case of steam jets, this device takes boiler steam, compresses the non-condensible vapors from the condenser and discharges the whole into a feed water heater working at atmospheric pressure. All of the heat except that lost in radiation and leakage is returned to the feed water and for that reason it would seem that the amount of steam required made little difference in the general economy of the whole plant. However, as pointed out previously, care must be taken to make certain that the available steam for heating the feed water is not excessive. One way of analyzing the steam consumption of such an apparatus as a steam jet air pump is as follows: Suppose the pump takes 3 per cent. of the main turbine steam and that the main unit is rated at 5,000 kilowatts or say 60,000 pounds of steam per hour, the steam jet, therefore, requires 1,800 pounds of steam per hour. If this steam were expanding through the same range, that is from boiler pressure down, in the main turbine, it would produce about 150 kilowatts per hour. This then, in a sense, is the power consumption of the air pump and is to be compared with the power that some other type of pump would require for the same condition.

Booster Pump

The efficiency of the booster pump for the low type jet and the supply pump for the barometric can be assumed as standard, consistent with good centrifugal pump design at a given head and quantity. However, the efficiency of the removal pump for the jet, owing to the slow entering water velocities in the impeller when pumping from a vacuum, is seldom over 50 per cent. The barometric, therefore, as far as power requirements are concerned is more efficient than the jet and less efficient than the surface. No condensate is reclaimed for boiler feed purposes in either case.

Where water supply is a serious problem some artificial method of cooling a given supply of circulating water is employed. This is done in several ways: Cooling towers of the natural draft enclosed type or of the natural draft open or rack type, forced draft, and combined forced and natural draft. In standard cooling tower practice it has been determined that with the air temperature at 75 degrees Fahr. and at 70 per cent. relative humidity, the most economical vacuum is 27 inches, based on a 30-inch barometer, or a vacuum having a temperature of 115 degrees Fahr.

Practical Cooling Limits

Rating all condensers on a 5-degree difference—surface, jet or barometric—thus requiring the minimum amount of water, it will be necesary to cool the water from 110 degrees Fahr. Commercially, under the given air conditions, it has been found practical to cool to only 85 degrees Fahr. or sometimes to 80 degrees Fahr., giving a 25 or 30-degree cooling range, which with steam at 1,000 B. t. u. per pound would require 25 and 33.3 pounds of water per pound of steam, respectively. The type of equipment to select would depend upon existing local conditions, such as space available and power consumption.

The natural draft open open type of cooler requires more ground space and can be placed only where the vapors and driftage will do no harm to surrounding buildings or property. This type requires a pumping head of approximately 30 feet and no other power. The natual draft enclosed chimney type takes less ground space, the chimney or stack is usually about 75 feet high.

Area of the Cooling Pond

It is impossible to state generally the area of a pond necessary for a given quantity of water, but generally speaking, at a working pressure on the spray nozzles of 6 to 7 pounds, a pond of 3 square feet per gallon of water sprayed will have to be used. The area of a natural cooling pond is obviously very large as the heat dissipated per square foot depends upon the relative humidity, the temperature of the water and the velocity of the air currents. These are naturally, on account of varied conditions, very discordant.

In any water cooling device 90 per cent. of the cooling effect is through evaporation and it is, therefore, vitally necessary that sufficient unsaturated air be given free access to the proper quantity of water. The air in all cases should go off the tower or pond in a saturated condition.

SETTING VALVES ON WHEELOCK ENGINES

READER'S QUERY—Kindly let me know if you have any information relating to the setting of the valves on the Jerome Wheelock engine.

W. P. SINCLAIR.

Medicine Hat.

The information requested above has been obtained from the manufacturer of these engines. It will be assumed that the valve motion and rods are all on the engine as shown in Fig. 1.

Exhaust Valves

In all cases the eccentric must follow the crank. The eccentric is first thrown as far as possible both ways and it is noted if the rocker arm A travels equal distances past the centre line; if it does not, lengthen or shorten the eccentric rod until it does.

Then place the eccentric on the extreme travel with the hook rod C in position. Drop a plumb line over the pin between the latch hook and the exhaust arm D. Measure from this line to the side of the valve spindle. Then throw the eccentric to the other extreme of its travel, drop the plumb over the other side of the pin and measure from the line to the side of the spindle. If these two measurements are not the same, adjust the hook rod C until they are.

This rod can only be adjusted on the rocker arm end and nothing less than one turn is possible. If adjustment is wanted closer than this to get the arm D to travel equal distances both ways, slightly lengthen or shorten eccentric rod B which has right and left hand threads. Set the exhaust arm E in the same manner as the arm D, any adjustment being obtained by lengthening or shortening the wiper rod G. After this is completed the three rods will be the proper length and the exhaust valves will be set.

Cut-off Gear

On Fig. 2, showing the cut-off arm P, note lines marked AB and CD; AB when plumb indicates the position of the cut-off valve when closed with the proper lap. CD, when plumb, indicates the

lead point, i.e., the point where the cut-off or steam valve is just opening.

The faces of the two cut-off arms have either lines or prick punch marks to correspond to Fig. 2. With the cut-off valves closed hang a plumb line over the face of each cut-off arm P and turn the eccentric dash pot studs I around until the line AB on each arm is plumb.

Care should be taken to have the two eccentric studs I set in the same relation to each other, either both towards the centre or towards the ends of the cylinder. The exhaust and cut-off arms are now set. To set the latch-hooks, throw the main eccentric ahead to the extreme position, then turn pin J at the frame or front end of the cylinder until the latch plate travels over the latch block 1-16 inch. Then throw the eccentric to the other extreme and set the other latch hook the same as above. Be sure studs J are in the same relation with one another.

To get the proper position for the eccentric on the crank shaft, put the engine on the forward dead centre, see that the front latch hook is engaged and turn the eccentric around on the shaft in the same direction as the engine runs until the line on the front cut-off arm, CD, is plumb. Secure the eccentric in this position.

Turn the engine the way it runs to the opposite centre and set the other cut-off arm the same, following the same instructions as before. If CD is not plumb on both ends adjust the eccentric a little to divide the difference between the two ends. After this is completed secure the eccentric on the shaft. This finishes the setting of the steam and exhaust valves.

Governor

On the front of the dash pots will be found two prick punch marks, one on the bottom of the dash pot and the other on the part that lifts. These punch marks should be the same distance apart when the dash pots are at rest.

If they are not, and the cut-off valves have been set correctly as described above, alter one set of marks to correspond to the other. Unhook the gab hook, S, and lift dash pot L till the line CD, Fig. 2, is plumb, as shown by a plumb line. Set a pair of compasses to the prick punch marks on the dash pot at this point. Raise the governor and fit a piece of wood into the slot in the governor top so that there is 5-16 inch between the bar connecting the governor arms and the top of the slot. Adjust the rod N until the dash pot trips off at the point when the prick punch marks are at the distance apart shown by the compasses. Set the dash pot M in the same manner, adjusting the rod O to trip dash pot off at the point where the prick punch marks are the distance apart shown by the compasses.

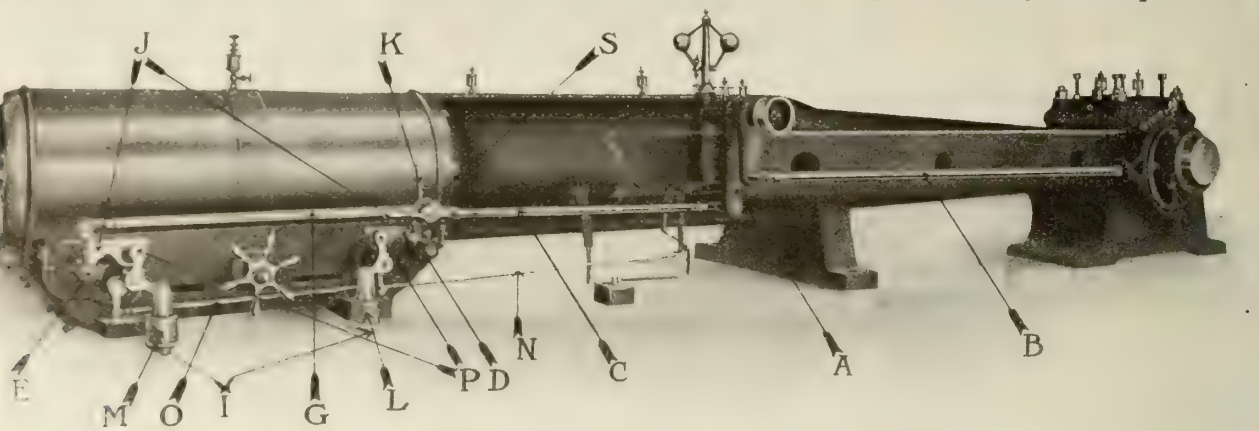

FIG. 1. STANDARD TYPE SINGLE CYLINDER WHEELOCK ENGINE.

FIG. 2. VALVE ARM

It is evident that the use of the prick punch marks and compasses is simply a more convenient way of working than with a plumb line on the valve arm, Fig. 2. Then drop the governor until there is 3-16 inch between the bottom of the cross bar and the bottom of the slot. Work the valve motion by means of a handle, K, and latch hooks should not hook on with the governor at this point. Be sure the latch hooks do not take hold when the governor is 3-16 inch from the bottom and also that they trip off when the governor is 5-16 inch from the top.

The speed at which the governor should run is 170 revolutions. Care should be taken to have all the joints of the governor rods free. Any binding in these will have a tendency to make

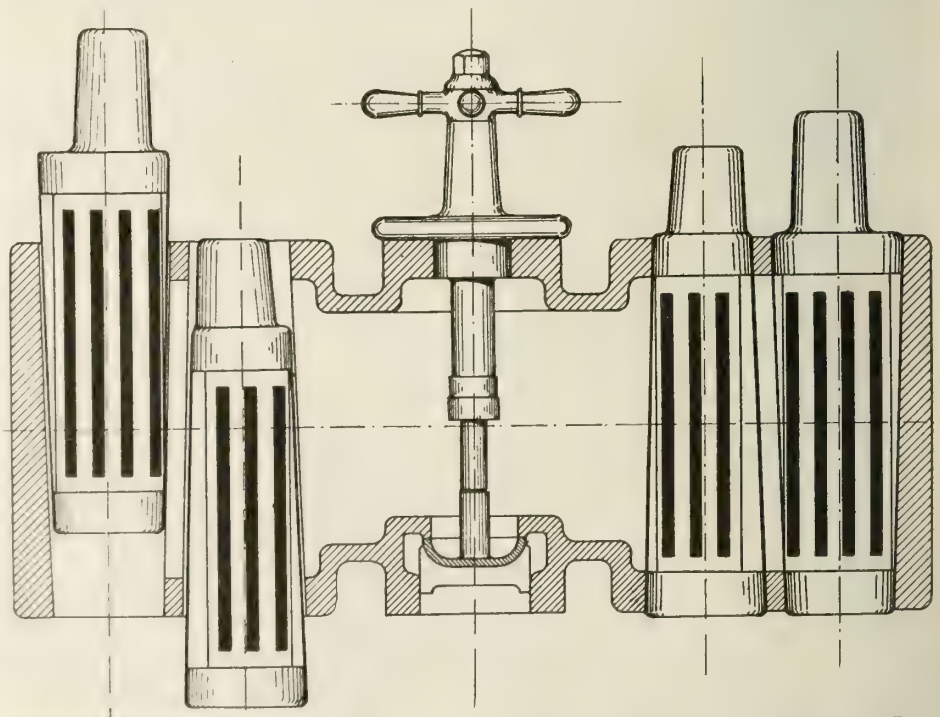

FIG. 3. ILLUSTRATION SHOWING THE REMOVAL OF VALVE PLUGS. NOTE: THEY COME OUT FROM OPPOSITE SIDES.

the governor unsteady. Should any of the acorn nuts screw a little too far and pinch the rods, put a small piece of lead in the bottom of the hole before screwing on. When valves are set in the shop the eccentric hook and wiper rods are all marked their proper lengths with chisel marks. The position of the eccentric on the shaft is also marked.

MODERN PRACTICE IN APPLYING GAS FIRING TO STEAM BOILERS*—II.

By T. M. Hunter, M.A., B.Sc.

Combustion of Gas

Apart from the question of calorific value, there is the question of the constituents of the gas. Two gases of similar calorific value can be shown which would give very different results on combustion. By-product producer gas, as is well known, is made by blowing steam and air blast into the producer fire, and the resulting gas contains hydrogen and CH_4. These gases, on burning, form respectively 1 and 2 cub. ft. of water vapor per cub. ft. of H_2 and CH_4, and the latent heat absorbed in forming this vapor, viz. 966 therms per lb. of vapor, is at present one of the inevitable losses in the use of the gas. The only way in which this heat could be recovered would be by cooling the chimney gases sufficiently to condense the water vapor, and this is impossible with our present economizers. To show the losses which are inevitable from this cause, the author gives the analyses of several gases, the net calorific value, and the number of therms lost by latent heat in the water vapor caused by combustion.

These analyses of gases, as in the case of any other analyses given in the paper, must be taken only as examples. They are analyses of gases with which the author has actually had to do, but it is well known that even on the same plant analyses of gas vary greatly from time to time.

	Coke-oven Gas. Per cent.	Blast-furnace Coke Gas. Per cent.	Moore Producer Gas. Per cent.	Mond Producer Gas. Per cent.
CO_2	——	12	12.7	16
CO	8.1	29	15.5	8
H_2	49.1	1.5	20.2	23.4
CH_4	32.6	0.7	2.2	3.2
C_2H_4	3.1	——	——	——
N_2	6.6	56.8	49.4	49.4
O_2	0.5	——	0.2	——
	Therms	Therms	Therms	Therms
Calorific value (cold gas)	540	112	132	130
Loss by latent heat in vapour of combustion	58½	1½	12½	17

This table shows the great value of the losses from this cause. The author has purposely chosen two producer gases of similar calorific value, in order to bring out the point that a gas is more valuable for boiler firing (or for combustion in any way) which has a greater proportion of CO to H_2, other things being equal. Producer buyers should look carefully into this point when specifying new plant. A certain amount of steam must be blown into the producer in order to recover the ammonia, but at present far more is used than the amount necessary for this purpose in order to cool the fire. The author believes that some other method should be adopted for this cooling. The Moore producer, mentioned above, does part of this cooling by means of a water jacket. It has been suggested that much of this cooling could be done by some method such as by blowing in boiler flue gases carrying, say, 15 per cent. of CO_2, and taking advantage of the absorption of heat which occurs when CO_2 is reduced to CO in the presence of heated carbon. This is known in America as the Eldred process. In this way the gas should be improved and much steam saved. The question, however, is still in the region of experiment.

Drying and Cleaning Gas

It is very important that the gas should be dry when burned. At any temperature from 0° to 100° C. gas will take up a known amount of water as vapor, and this amount can be found in an air-saturation table. If the gas has been cooled or washed in water, it is reasonable to assume that it is saturated with water to the amount corresponding to the lowest temperature to which the gas has been brought. As an example of the amount of water carried in this way, the author had recently to use, at 15° C. and 55° C. respectively, the two producer gases described in the above table. The former gas carried under 2 per cent by volume of water vapor, and the latter carried 15½ per cent. This vapor must all be heated when the gas is burned, and it not only lowers the flame temperature, but also is responsible for carrying to the chimney a large quantity of sensible heat.

To show the actual loss from this cause, let us assume that we have cleaned blast-furnace gas from the same furnace, in one instance at atmospheric temperature with 12 to 15 grammes per cub. metre of water vapor, and in the other instance gas saturated at 70° C., carrying about 362 grammes per cub. metre. The analysis of the gas at 0° C. and atmospheric pressure is:

Per cent.		Calorific Value
CO	29	965 calories per cub. metre 107 therms per cub. ft.
H_2	3	
CO_2	8	
N_2	60	

In both cases the gas is to be burnt under boilers with an excess of air of 25 per cent.

We have to ascertain, first of all, the air necessary for the combustion of this gas without excess of air, which is shown by the following table in cubic metres:

	1 cub. m. of Gas	Oxygen needed	CO_2	H_2O	N_2
H_2	0.03	0.015	——	0.03	——
CO	0.029	0.145	0.29	——	——
CO_2	0.08	——	0.08	——	——
N_2	0.60	——	——	——	0.60
	1.00	0.160	0.37	0.03	0.60

Air required:

$0.160 \times 4.77 = 0.78$ carrying N_2....0.62

Total N_2 ....1.22 cub. m

25 per cent. excess of air, $0.78 \times 0.25 = 0.195$ cub. metre.

The combustion temperature of this gas when burnt with an excess of air of 25 per cent. is 1,294° C., found thus, using the Le Chatelier formula:

Air and N_2	$1.415 \times (0.303t + 0.000027t^2)$
H_2O	$0.03 \times (0.34t + 0.00015t^2)$
CO_2	$0.37 \times (0.37t + 0.00022t^2)$
Total ..	$0.5758t + 0.0001241t^2 = 965$
	$t = 1{,}294°$ C.

Now take the gas at 70° C. Its temperature is about 55 degrees C. higher than atmospheric temperature, so that the additional sensible heat per cubic metre is 3 therms. This raises the calorific value of the gas to 110 therms. To this must be added the heat in the water vapor accompanying the gas, so that the calorific value of the gas plus the water vapor will be 113 therms or 998 calories. One cubic metre of aqueous vapor at 70° C. weighs 644 grammes (1 cub. metre of water vapor at 0° C. = 810 grammes: at 70° C. $\frac{810 \times 273}{273+70}$), so that 362 grammes of vapor carried by the gas will correspond to 0.562 cub. metres, and the combustion temperature is found thus:

Air and N_2	$1.415(0.303t + 0.000027t^2)$
H_2O	$0.592(0.34t + 0.00015t^2)$
CO_2	$0.37\ (0.37t + 0.00022t^2)$
Total ...	$0.775\ t + 0.000208\ t^2 = 998.$
	$t = 1{,}010°$ C.

This shows that there is a drop of 284° C. in the combustion temperature, which, of course, is a very serious matter. It is much more difficult to obtain complete combustion of this mixture of aqueous vapor and gas with an excess of air of 25 per cent. than if gas alone is dealt with. It is also a well-known fact that the efficiency of a boiler depends in the first instance on the initial temperature of combustion, and if the latter is lower the efficiency of the boiler is certain to decrease. The first thing to be affected will be the evaporation per square foot of heating surface, which is certain to be

*A paper presented before the Institution of Electrical Engineers.

considerably smaller if wet gas is used than with dry gas.

We have next to consider the effect of the water vapor on the efficiency of the boiler. From our former calculations the formula representing the loss is, in the case of the dry gas, $0.5758\,t + 0.0001241\,t^2$, and in the case of the wet gas $0.775\,t + 0.000208\,t^2$.

Let us assume that it would be possible to burn completely the dry and the wet gas with an excess of air of 25 per cent. and to pass the waste gas to the stack in both instances at a temperature of 250° C. The losses through waste heat in the case of dry gas would be $0.5758 \times (250 - 15) + 0.0001242 \times (250^2 - 15^2 = 204$ calories and in the case of the wet gas $.775 \times (250 - 15) + 0.000208 \times (250^2 - 15^2)$ 297 calories per cub. metre of the gas burned. The loss through waste gas for dry gas would be 21 per cent. of the total value of the gas, and for wet gas 29.8 per cent. Or, in other works, the presence of the water in the gas will cause an unavoidable and irredeemable loss of 8.8 per cent., in addition to the loss by the reduced flame temperature. Assuming in both cases 5 per cent. loss through radiation and conduction, the actual efficiency for dry gas would be 74 per cent., and for the wet gas 65.2 per cent., which is equivalent to a drop in the output obtainable from the same quantity of gas amounting to 12 per cent.

Effect on Evaporation

So far as regards the efficiency, but it will also be worth while to consider the evaporation obtainable in both cases. Let us assume that in both cases the boiler is working on its maximum load—that is to say, that the boiler flues pass the maximum quantities of gas and air which the chimney draught can convey at the most favorable position of the damper. Let us assume that we are dealing with a 30 ft. x 8 ft. Lancashire boiler and that with a dry gas under the above described circumstances the highest possible evaporation was 6,000 lb. of water from and at 212° F. As the total efficiency of the boiler is 74 per cent., the total quantity of gas necessary in order to provide this evaporation contains 7,830,000 therms. At 107 therms per cub. ft. 71,000 cub. ft. of gas must be burnt per hour in order to obtain this evaporation. It was found above that for each cubic foot of gas 0.975 cub. ft. of air are necessary for complete combustion with an excess of air of 25 per cent. The air passed through the boiler will be 69,000 cub. ft. per hour. In order to facilitate our calculation let us assume that the weights of the gas and the air are the same. Then the total weight of 140,000 cub. ft. of air and gas will be $140{,}000 \times 1.293$ oz. $= 11{,}310$ lb., which represents the total weight of products of combustion that the boiler can possibly pass. Now at 70° C. each cubic foot of gas carries 0.0228 lb. of water, whilst the weight of the products of combustion from each cubic foot of dry gas will be 1.975×1.293 oz. $= 0.16$ lb. The weight of the products of combustion of wet gas is increased by 0.0228 lb. for each cubic foot of gas, giving a total weight of 0.1828 lb. for each cubic foot of dry gas plus water. The boiler is not capable of passing more than 11,310 lb. per hour, so that the maximum amount of gas to be dealt with would be $11{,}310 \div 0.1828 = 62{,}000$ cub. ft. per hour. The total calorific value of the hot gas is 113 therms per cub. ft. The total heat admitted is $62{,}000 \times 113$, or 7,000,000 therms; the possible efficiency as above is 65.2 per cent.; the heat in the steam is, therefore, 4,670,000 therms, which corresponds to 4,725 lb. from and at 212° F.

This somewhat lengthy calculation is useful, as it shows that the simple presence of water in the gas can, under otherwise absolutely equal conditions, result in

(1) A drop of efficiency of nearly 9 per cent.
(2) A drop in evaporation of more than 21 per cent.
(3) The loss due to lower flame temperature, which the author has not attempted to calculate

From these calculations it is evident that an engineer who has to specify a producer plant, or a gas-cleaning plant, where washing of the gas is part of the process, should take care to specify the maximum amount of water vapor allowable in the gas supplied.

Effect of Dust

Contrary to a frequently expressed opinion the author does not believe that the dust in itself impairs seriously the heating value of blast-furnace gas; and the uncleaned gas has the advantage that it contains the sensible heat. The dust, however, may seriously affect the efficiency of the boiler. If two Lancashire boilers are run side by side, the one on cleaned and the other on uncleaned blast-furnace gas, it will be found that at first the results as regards both evaporation and efficiency are about the same. Soon dust will start to accumulate in the boiler flues, and as this dust is an insulating agent it will impair both the evaporation and the efficiency. After four or six weeks the dust accumulates in such large quantities that the evaporation falls and combustion may even take place partly in the stack instead of under the boiler. Where Lancashire boilers are to be fired, it will, therefore, generally pay to instal a gas-cleaning plant, even at the expense of the sensible heat which is lost in the cleaning process.

Conditions are much more favorable with water-tube boilers, as with these it is often possible to clean the tubes without stopping the boiler. If liberal use is made of the steam lance, the proposition to put in a cleaning plant will certainly not be such a favorable one as in the case of Lancashire boilers

It is not proposed here to enter into the advantages and disadvantages of the various systems of dry or wet cleaning. The ultimate choice in each case will depend on the first cost of plants and on the cost of attendance and maintenance. Heavy charges are involved for power consumption and for interest and depreciation on the capital outlay. But, whatever the cost should be, it must be borne in mind that the cheapest plant is not worth having unless it fulfils the following conditions:

(1) The gas must be clean.
(2) It must be dry, and this is even more important than the cleanness.

In some cases where the gas can be cooled to a temperature of 80° C. without water injection, and where the ores contain only a small percentage of moisture, it is possible with a dry cleaning plant to obtain a dry, hot gas; whereas, where wet cleaning processes are used, or where water is injected for the purposes of cooling the gas, the gas is saturated and this water has to be eliminated.

So far as the author can discover the cost of cleaning gas, inclusive of all charges, is about 4c per 35,000 cub. ft., and is practically the same whether the wet or the dry process is used.

The sensible heat in blast-furnace gas per cubic foot is approximately as follows:

Temperature of gas, C.....	200°	250°	300°	350°	400°
Sensible heat, therms per cub.ft..	7	9	11	13	15

As cold blast-furnace gas varies from about 90 to 110 therms per cub. ft., this sensible heat is a large percentage of the total heat of the gas. Firing water-tube boilers with properly designed burners, and using the steam lance, say, twice a day to clean the tubes, the efficiency with uncleaned gas is certainly within 10 per cent. of the efficiency with cleaned gas—probably within 6 per cent. On the other hand, with Lancashire boilers the average efficiency over 4 or 6 weeks with uncleaned gas is very considerably lower than with cleaned gas.

The decision as to whether it will pay to clean gas must, therefore, be made for each case separately, and depends on the peculiarities of the gas and of the dust, as well as on the kind of boilers used.

Heat Transfer

Gaseous fuel as usually burned does not give the intense local heat and the heat-radiating surface of the coal fire. Rather the problem is that of a very hot gas which is cooled gradually as it travels through the boiler. It is like the problem of a coal-fired boiler with the fire-grate entirely outside.

The transfer of heat through a steel wall from hot gases to water consists of three parts—transfer of heat from gas to metal, transfer of heat through metal, transfer of heat from metal to water. The resistance to the transfer of heat in the second and third parts is exceedingly small when compared with the resistance to the transfer of heat from gases to metal. It is calculated for one case that the resistance to transfer of heat from gas to metal was 622 times the resistance to heat passing through the steel. This shows that the advantage to be gained by fitting, say, copper tubes instead of steel would be very small indeed. Again, the transfer from metal to water, if the

metal has a clean surface, is also negligible compared with the gas-metal transfer. If, however, the metal carries scale on its surface the case is very different. Scale ¼ in. thick, assuming the scale to have the same conductivity as plaster of Paris, of which the specific resistance to the conduction of heat is 108 times that of iron, would add resistance to heat transfer equal to 18 per cent. of the resistance of transfer from gases to steel.

READERS' QUERY

Question.—Will you kindly advise me if there is any special formula for calculating the working pressure on a furnace for a vertical tubular boiler. Would you also give me the calculation of the following:

Furnace 46 ins. dia., 48 ins. high, ⅜ in. plate with staybolts ⅞ in. dia., and 4½ x 4½ in. pitch.—Reader's Query.

Answer.—The portions of the Ontario Boiler Act abstracted below cover this portion of the design of vertical boilers quite fully:

Section 63.—Internally Fired Furnaces or Parts of Boilers (other than ordinary fire tubes) subjected to compression.

The furnace plates in plain circular internally fired furnaces, not exceeding 42 ins. in diameter, if not found sufficiently strong must be stayed as flat surfaces, allowing in the calculations for such 75 per cent. of the value of the resistance to collapse as found by the following formula, the pitch of stays being computed by the rule for flat surfaces, but the pitch shall in no case exceed eight inches on the furnace plate. For furnaces over 42 inches in diameter no allowance for value of resistance to collapse shall be made. Care must be taken not to reduce the efficiency of the riveted joint when applying these stays

$$B = CT^2 \div (L_1 + 1)\ Dr$$

Where,—

Dr = outside diameter of furnace in inches.

T = thickness of plate in inches.

L_1 = length of furnace in feet, or length between rings.

B = working pressure per sq. in. which must not exceed that found by the limiting formula as follows:

$$\frac{10{,}000\ T}{Dr} = B$$

C = A constant according to the following circumstances:

Furnaces with butt joints and rivet holes punched small and reamed out in place.

112,500 where the longitudinal seams are double riveted, and fitted with single butt straps.

100,000 where the longitudinal seam is single riveted, and fitted with single butt strap.

112,500 where the longitudinal seam is single riveted and fitted with double butt straps, or where seam is welded.

Furnaces with lamp joints and rivet holes punched small and reamed out in place:—

96,000 where the longitudinal seams are double riveted.

87,500 where the seams are single riveted.

Section 55 Flat Surfaces

The formula for staying surfaces mentioned above is as follows:

The maximum stress allowable on flat plates supported by stays shall be determined by the following formula:

All stayed surfaces formed to a curve the radius of which is over 21 ins., excepting surfaces otherwise provided for, shall be deemed flat surfaces.

Working pressure = $ct^2 \div p^2$.

Where,—

t = thickness of plate in sixteenths of an inch where doubling plates are used, for "t" take .75 of the combined thickness of both plates.

p = pitch of stays in inches when equally spaced in both directions.

C = 112 for screw stays, with riveted heads, plates seven-sixteenths of an inch thick and under.

C = 120 for screw stays, with riveted heads, plates over seven-sixteenths of an inch thick.

C = 120 for screw stays, with nut outside sheet, plates seven-sixteenths of an inch thick and under.

C = 125 for screw stays with nut outside sheet, plates over seven-sixteenths of an inch thick and under nine-sixteenths of an inch.

C = 135 for screw stays with nut outside sheet, plates nine-sixteenths of an inch thick and over.

C = 175 for stays with double nuts, having one nut on the inside and one nut on the outside of plate, without washers or doubling plates.

C = 160 for stays fitted with washers or doubling strips which have a thickness of at least the thickness of the plate, and a diameter of at least .5 of the greatest pitch of stay, riveted to the outside of the plates, and stays having one nut inside of the plate and one nut outside of the washer, or doubling strip for "t" take 72 per cent. of the combined thickness of the plate and washer or plate and doubling strip.

C = 200 for stays fitted with doubling strips which have a thickness equal to at least the thickness of the plate reinforced, and covering the full area braced (up to the curvatum of the flange, if any) riveted to the inside of the plate and stays having one nut outside and one inside of the plate. Doubling plates to be substantially riveted. For "t" take 72 per cent. of the combined thickness of the two plates.

C = 200 for stays with plates stiffened with tees or angle bars having a thickness of at least the thickness of plate and depth of web at least one-fourth of the greatest pitch of these stays and substantially riveted to the plates and stays having one nut inside, bearing on washers fitted to the edges of the web, that are at right angles to the plate. For "t" take 72 per cent. of the combined thickness of web and plate.

Since the diameter of the furnace for which calculations are requested is over 42 ins., the working pressure cannot be calculated from the formula given in Section 63, but must be figured according to that given in Section 55, as follows: Furnace 46" dia., 48" high, ⅜" plate with stay bolts ⅞" dia. and 4½" x 4½" pitch.

Working pressure = $Ct^2 \div p^2$.

Where

t = 6

p = 4½"

c = 112

This works out at about 199 lbs. per sq. in. for this particular part of the boiler.

ELECTRIC POWER BY WIND

Windmills to generate enough electricity for a farm, or even for a small municipality, are now in successful operation, according to the "Electrical Experimenter." Indeed, such plants can be made to generate hundreds of horsepower. This magazine thus describes a plant suited to a small farm:

"In operation the power vanes are each rotated on their respective bearings in such a manner as to expose them to the wind at the angle of greatest efficiency at every degree of the circle, while traveling with, across and against the wind, there being about 30 degrees only of the circle when the vane comes against the wind edgewise to a degree where it is not efficient.

"Another feature of this design of wind-power wheel is the automatic controllability. By means of a centrifugal two-ball governor or by a resistance type electric governor, the vanes are varied in their angle to the wind in case of high wind velocity, so that the motion of the wheel is kept from running above a given speed. This protects both the power plant and machinery from unnecessary wear and strain.

"The automatic means for stopping the mill when the storage batteries are charged and throwing it in the wind when any given number of ampere-hours have been discharged, assure perpetual and abundant service without further expense or attention, except oil for the plant once a year, distilled or rain water for the batteries, and reasonable attention to the generator.

"The small farm type plant is automatic, starting and stopping according to the condition of the storage batteries. It charges the batteries about once a week on the average."

R. L. WIGG and L. R. Ferguson have carried out some interesting experiments bearing upon the effect of sea water on concrete. They have found, among other things, that the character of the workmanship has an important bearing on the ability of concrete to resist the action of sea water. Only contractors of experience, employing competent men, should, they urge, undertake important work in sea water. The difficulties usually encountered cannot be overcome by any but the best of organizations thoroughly equipped with the necessary tools and machinery.

Power Transmission Section

SPEED REDUCTION GEAR

RECENT developments in the use of prime movers having high rotational speeds have necessitated the employment, in many cases, of some form of speed reduction gear. The difficulties surrounding this application of gearing are well known. High peripheral speeds, proper lubrication, floor space occupied and lack of convenience and general adaptability combine to form a problem trying the designers' ingenuity.

A new form of speed reduction gear has recently been developed by the Pool Engineering Co., of Baltimore, the design being such that it may be used for either step up or step down service.

The high efficiency of the gear has been shown in a recent test where the gear gave an efficiency of 98.5 per cent. as an average of five readings.

The torque of a direct current motor was measured by means of a Prony brake at a certain number of armature amperes, volts and field amperes, the speed also being measured. The motor

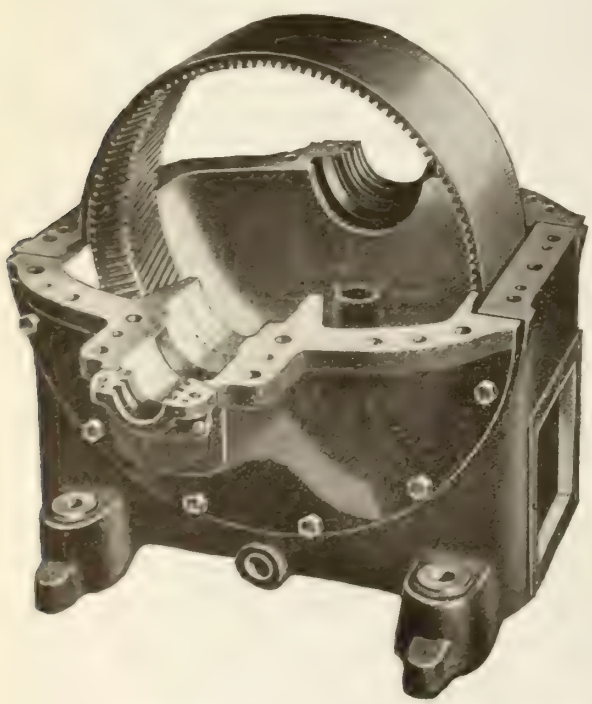

FIG. 1. LOWER HALF OF CASING SHOWING INTERNAL GEAR IN POSITION.

Prony brake attached to the gear. The load was then adjusted to give the same electrical readings and the torque then was then coupled to the gear and the read. The ratio of this second torque to the first multiplied by the gear ratio gave the efficiency.

$$\text{Efficiency} = T_1 \div T_2 \times 6.666$$

The totally enclosed feature makes it impossible for the workman to get his fingers or clothing caught in any rotating part or gear. This feature also makes for low maintenance cost and permits its use in wet, dirty, dusty or gritty places.

Low Maintenance Cost

After installation there is little or no maintenance expense attached to the operation of this gear. The only attention needed is to see that an adequate supply of oil is in the reservoir. This may be contrasted with a belt or chain drive where constant attention is needed due to the stretching of belts or the wear of chains and sprockets.

Owing to the self-contained nature of this gear the cost of installation is very slight. It is only necessary to provide a firm foundation and to insure that the alignment of the gear and the driving and driven unit is perfect. When mounted in accordance with sound engineering practice this reduction gear is practically noiseless and works without vibration.

The casing is horizontally split, so that by the removal of the casing bolts the tops may be removed for inspection without disturbing the gears or shafting in any way.

As the high speed and low speed shafts are in axial alignment and all tooth pressures are balanced there is no tendency to deflect the shafts and produce unequal stresses on the bearings. The bearings merely have to support the weight of the rotating members. In the case of motors connected to chains or belts there is always considerable side pull on the bearings, this causing wear and often heating.

The high and low speed shafts are each independently supported by the casing. The low speed shaft is sup by the casing. The low speed shaft is supported at each end by heavy duty S.K.F. ball bearings. One end of the high speed shaft is supported in a babbitt split bearing and the other end in a

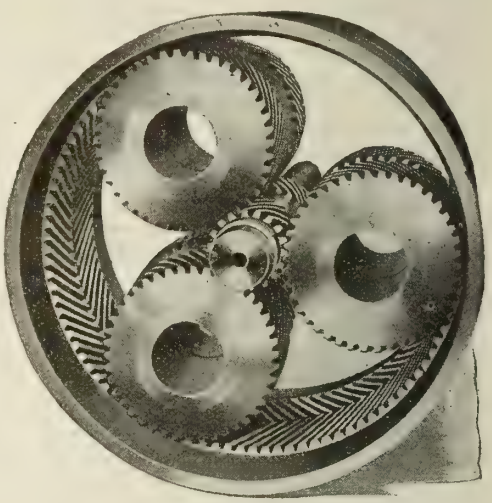

FIG. 2. GEAR MEMBERS.

bronze bushing inside the cage, which forms a part of the low speed member. The pinion is cut integral with the high speed shaft and is allowed to float and seek its equilibrium between the intermediate gears.

Three Line Tooth Contact

Another advantage of the construction adopted is that there are three lines of tooth contact as compared to the one line of contact of the ordinary herringbone and pinion. This results in a lower tooth pressure for equal horse-power transmitted and consequently in a longer life.

The gear will drive in either direction without any changes and both the high and low speed shafts revolve in the same direction. Speeds as high as 6,000 r.p.m. and over are successfully handled.

Turbine Drive

The high economy of the modern steam turbine makes it a desirable prime mover for the operation of various machines. Steam turbines to be economical must necessarily run at high speeds, yet many machines, such as centrifugal pumps, fans, generators, etc., require a speed much slower than that of the steam turbine. To reduce the speed of one or increase the speed of the other is a compromise which materially lowers the efficiency of both

units. The mechanical speed reduction gear offers an admirable solution of this problem.

The extensive application of electricity throughout the industrial world has demonstrated the efficiency of motor drive. It is impossible, however, to secure a really slow speed motor and it will often be found advisable to purchase a high speed one and to drive through a reduction gear.

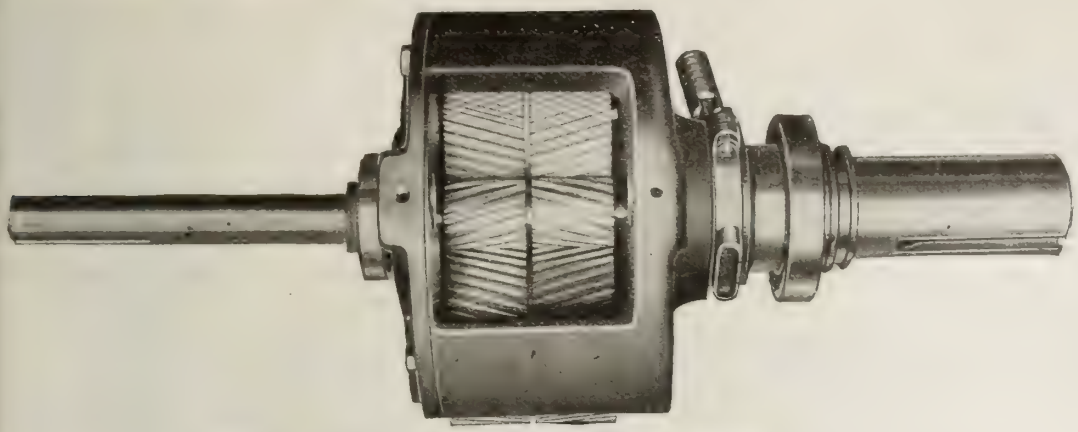

FIG. 3. GENERAL ASSEMBLY SHOWING PINION AND INTERMEDIATE GEARS (ONE INTERMEDIATE GEAR BEING REMOVED FOR CLEARNESS).

Construction

The gear members are cut on a gear generator which produces a true involute stub tooth of great accuracy and finish. These gears are not subjected to any process such as filing, scraping or polishing after being cut as this is unnecessary.

This speed reduction gear consists of an internal double helical gear, see Fig.1, made of a special analysis open hearth steel, forging heat treated to increase its ductility and to insure uniform hardness; a double helical pinion, Fig. 2, cut integral with the high speed shaft; intermediate double-helical gears shown in the same illustration made of high carbon steel forgings with large bronze bearings, mouted on hardened and ground steel shafts secured to the cast-steel slow speed member.

The high speed shaft and pinion as well as the slow speed members carrying the intermediate gears are accurately ground all over and are carefully tested for static and dynamic balance before being assembled.

The casing is made of tough, grey, cast iron, horizontally split. It is very substantial and well ribbed to provide a rigid support for the gear members, this insuring efficient and quiet operation.

The high-speed shaft has a central passage through which the oil is pumped, and continuous radial passages in the pinion. The oil after lubricating the gears and bearings is drained to the main oil reservoir in the base where it is filtered, cooled, returned to the pump and used over again.

Operation

The internal gear is held rigidly in place in the casing and is kept from turning by means of two keys which slip into two keyways in the gear and casing. The pinion meshes with the intermediate gears and the intermediate gears mesh with the internal gears.

Let us assume that we wish to drive a low speed machine with a high speed mover. The prime mover should be connected with the pinion shaft; this causes the pinion shaft to rotate and turn the intermediate or planetary gears. As the internal gear is held stationary, the intermediate gears must not only rotate but must of necessity revolve about the pinion shaft. This causes the low speed shaft, connected to the spider housing the intermediate gears, to rotate at the desired speed.

FIG. 4. TURBO-GEAR MOTOR LINE SHAFT DRIVE. 100 H.P. GEAR. SPEED REDUCTION 730-122 R.P.M.

Motor Line Shaft Drive

A very interesting application is found in Fig. 4, which shows two 100 h.p. motors direct connected to the line shafts through this device. It will be noticed that the gears and motors are mounted on base plates set upon concrete pillars.

An interesting application of a direct connected reduction gear and steam turbine is shown in Fig. 5. This illustrates a 100 horsepower turbo-gear direct connected to a Terry steam turbine reducing the turbine speed from 3,600 to 440 rev. per min., which is the speed of the driven unit—in this case a blower.

Two of the most noticeable features of this outfit are its compact and symmetrical appearance, together with the absence of offset shafts, the driving and driven shafts being in the same straight line. These features result in a considerable saving of floor space, as well as permitting a better grouping of the machines.

It is frequently found desirable to drive centrifugal pumps, fans, etc., with a law speed prime mover such as a gas engine. Fig. 6 shows an installation of this character where the engine speed is stepped up to the desired pump speed.

THE STEAM GUN

AT a time when many novel devices are being employed to hurl death and destruction at an enemy, it is interesting to recall that amongst the inventions of that remarkable genius, Jacob Perkins, was a steam mitrailleuse, which astonished the good people of 1826 no little, but which was never used to any more serious purpose. Jacob Perkins was the pioneer of really high pressure steam. A mere 200 lb. or so was nothing to him; he preferred to employ 1,000 lb., and spoke lightly of a hundred atmospheres.

The pressure used in the gun was probably irregular, but according to Perkins'

own statement it was at least 750 lb. The whole thing was extremely ingenious. The steam generator consisted of a stout steel tube 3 in. diameter and 6 ft. long, provided with headers into which a number of smaller tubes were welded. With the two headers were connected the ends of a coil of stout iron tube, 80 ft. in developed length, which was placed in a furnace. The coil and headers and pipes were filled with water, which circulated under the influence of the heat, and ultimately reached a very high temperature and pressure, the amount of which was controlled by a damper, regulated by the expansion and contraction of part of the tube system. When the generator was sufficiently hot water was injected into the space outside the tubes by a hand pump, and was rapidly converted into steam which was conveyed to the gun.

The gun was not more than a tube with a valve near the breech end, and just in front of the valve a hopper provided with a shutter for the bullets. On pressing the discharging lever the steam struck the bullet in the barrel and drove it out with considerable force. It was reported in 1826 that the gun had been brought to such perfection that it was exhibited before the Duke of Wellington.

Lead balls of an ounce in weight were driven at a range of 35 yards through an iron plate ¼ in. thick, or through eleven planks of hard wood one inch thick and placed one inch apart. But what most surprised the spectators was that the bullets issued in such rapid succession that a long plank was almost sawn in two longitudinally when the gun was swung round slowly in front of it. The piece with its generator was much too cumbersome and unwieldly for the field, but as an example of the use of very high pressure steam the invention is full of interest. Perkins was miles before his time if ever a man was, but his descendants are already beginning to see signs of the advent of much higher pressures than those in common use, even nearly a century after Perkins' time.—*The Engineer.*

FIRST CONCRETE SHIP TRIAL TRIP

THE Namsenfjords recently ran her trial trip. She is the first reinforced concrete full-powered vessel, built in Norway, to be completed. She has a length of 84 feet by 20 feet by 11 feet 6 inches draught, on which she carries 200 tons of cargo, and with her 80-horse-power Bolinder engine develops a speed of about 7½ knots. It was found on trial that vibration was practically non-existent, which speaks well for the method and material of construction. While on trial the vessel's sea-going qualities were thoroughly tested, and she behaved excellently. A large hold is arranged for, and a maximum-sized hatch will facilitate the loading and discharging of her bulky packages. The cargo will be dealt with by a powerful motor winch. The crew's quarters are forward, and the captain, mate, and engineers will be berthed aft on deck. Reinforced concrete vessels should prove valuable assets to those countries which have lost vessels during the war. If steel and wood were plentiful and could be released for commercial work, there is every probability that concrete construction for marine purposes would not have been studied to the extent that it has been. This development will no doubt prove to be one of the benefits the allies will gain through the war. There is a limit to the output of steel and properly-seasoned timber, but practically none to the production of cement.

There are, of course, drawbacks to every new industry, but, so far as can be determined, advocates of the reinforced concrete vessels believe they have only one, viz., heavier hulls than if steel or timber were employed. But against this, it is pointed out, there are advantages, such as increased cubic capacity, cost of upkeep practically nil, and reduced cost of repairs in the event of damage.

For quite a considerable period tug owners have been anxious to employ tugs fitted with oil engines in preference to steam engines on account of the reduced cost of running, but so far there has been a slight drawback—the reduced weight of machinery. With a cargo vessel this reduced weight is naturally of considerable benefit to owners, but with a tug, weight is essential. A reinforced concrete tug, fitted with an oil engine, would have a somewhat similar displacement to a steel vessel fitted with steam machinery. As a consequence, provided the experimental vessels now under construction in this country prove a success, tug owners may be expected to consider the oil-engine concrete tug proposition on really serious lines.—London Shipping World.

ICE PLANT MEN ARE WARNED TO BE SAVING OF AMMONIA

THE United States Food Administration has issued an appeal to owners and operators of ice making and refrigerating plants to do everything within their power to stop all waste and leakage in their use of ammonia.

"During 1918 the Government should have for munitions alone 20,000,000 pounds of ammonia more than it is possible to make by working all the plants producing ammonia in this country to their maximum capacity," the Food Administration declares in this appeal.

Shortage in Summer

"This shortage will be greatly increased by the ammonia that will be furnished ice making and refrigerating plants, but it is hoped that by appealing to the patriotism and business sense of all ammonia users, and urging them to stop all waste and leakage, that the usual consumption may be curtailed to such an extent as will permit at least the most efficient plants to run; particularly where natural ice is not available.

"A saving of 25 per cent. in the ammonia consumption of ice and refrigerating plants would mean several million pounds annually for munitions. Each pound will make 20 hand grenades. Late returns show this saving can be accomplished if all will stop the leaks."

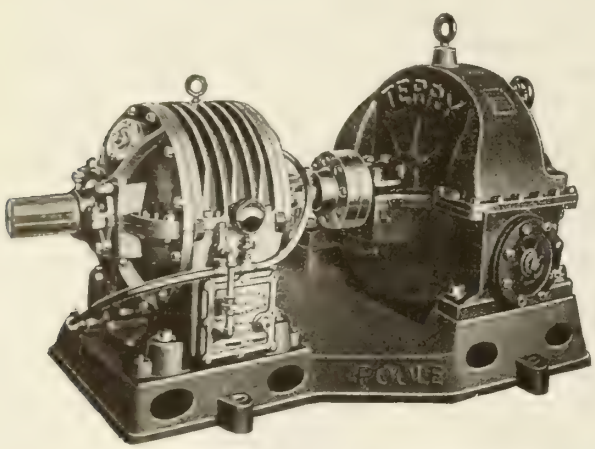

FIG. 5. STANDARD TURBINE INSTALLATION.

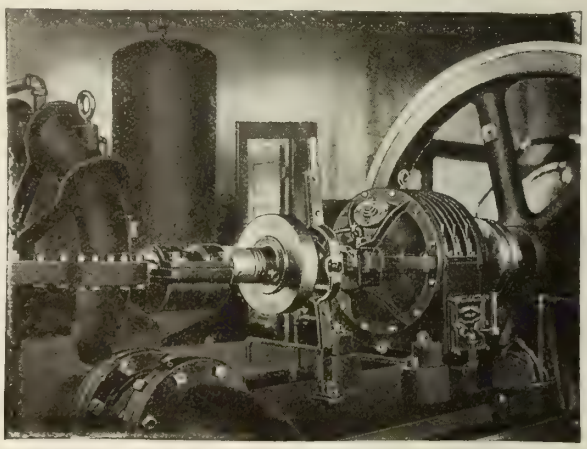

FIG. 6. 100 H.P. INSTALLATION STEPPING UP ENGINE SPEED TO THAT REQUIRED FOR PUMP.

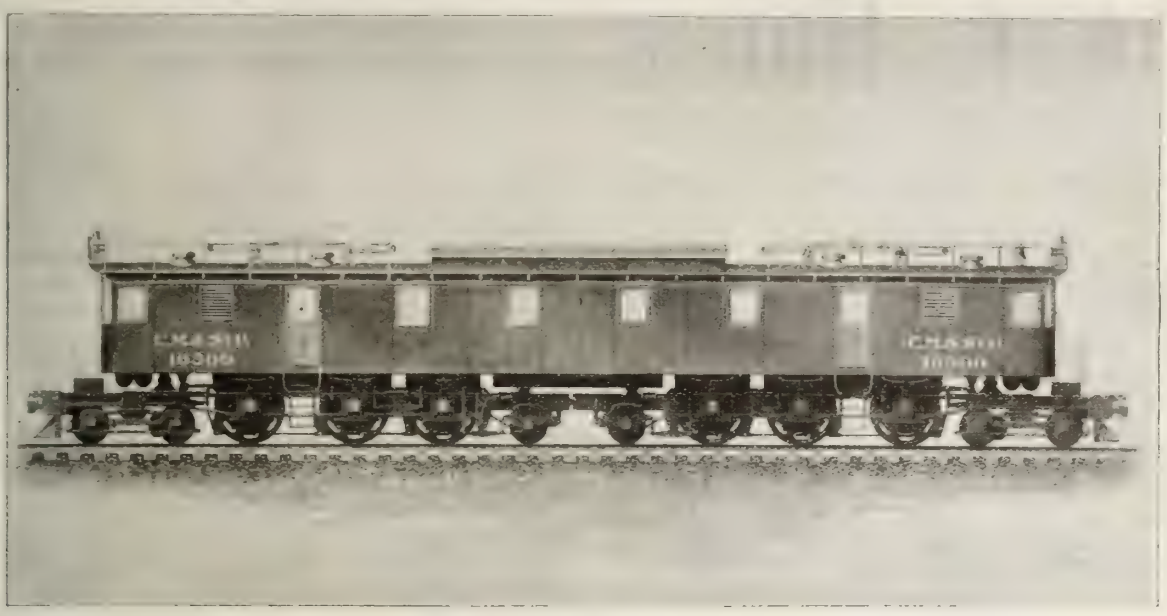
CANADIAN manufacturers now produce 800,000 complete shells every week, which is more than was produced, before the war, by any nation except Germany.

POWERFUL ELECTRIC PASSENGER LOCOMOTIVES FOR THE CHICAGO, MILWAUKEE & ST. PAUL RAILWAY

The concentration of enormous horsepower in a single locomotive unit has long been the recognized tendency in railway practice. This originated from considerations of crew-economy and the greater efficiency of large units. The limits of the two-man crew have been reached, while further increases in size will yield but small improvements in efficiency. Recourse must be had to some new form of motive power if necessary increases in hauling capacity are to be made.

It is fortunate in many ways that electricity has thoroughly proven itself for this purpose. On the Chicago, Milwaukee & St. Paul Railway, its use over the 440 miles of line over the Rocky Mountains has been so satisfactory in operating efficiency, hauling heavier trains and keeping traffic moving in all weathers that the railroad's decision has recently been made to electrify another mountain division—the 211 miles from Othello, Washington, over the Cascade Range to Seattle and Tacoma. With the completion of this work, a distance equal to that from New York to Cleveland will be under electrical operation. To handle passenger traffic over this and the Rocky Mountain division, the St. Paul has ordered ten electric locomotives.

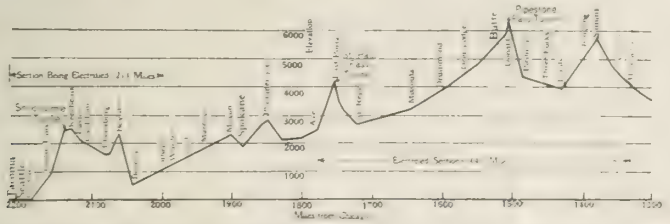
These locomotives will have a length of 90 ft. over couplings, and will weigh 266 tons when ready for service. Each machine will have a single cab, extending over practically its entire length. The running gear consists of two units of the familiar "Pacific" type placed back to back. Each will have a four-wheel guiding truck, three driving axles with 68-inch driving wheels, and a two-wheel trailing truck, connected by a heavy link and the cab will be free from pulling strains.



3,200 H.P. ELECTRIC LOCOMOTIVE.

Each locomotive will carry twelve motors, arranged in pairs permanently connected in series, each pair being geared to the same driving axle through a quill, whose spring mounting gives a certain amount of flexibility for cushioning the road and pulling shocks. By this means the only weight not spring-supported is that of the wheels, axles and journal-boxes.

These will be the most powerful locomotives in passenger service. Each can haul a 950-ton train of 12 coaches over the St. Paul's entire mountain section at the same schedule speed made by two or three steam engines. Each locomotive can deliver 3,200 h.p. indefinitely, and 4,000 h.p. for one hour. At starting, a pull of 112,000 lbs. can be exerted on a train, while the normal maximum speed on level track is 60 miles per hour and up a 2 per cent. grade, is 25 miles per hour.



PROFILE CHICAGO, MILWAUKEE AND ST. PAUL RAILWAY.

One great advantage of the electric locomotive is that it will maintain its efficiency over a wide range of speeds. For these locomotives there are nine economical running speeds, varying from 8 to 56 miles per hour. These are secured by various series and parallel groupings of the motors, and by placing shunts around the fields.

Of cardinal importance in these locomotives are the arrangements for regenerative braking. Due to long grades, wear on brake-shoes was excessive, and the possibility of accident from brake-failure was always present. Where the locomotive motors become generators there is no difficulty in bringing a train down the longest grade at a higher speed than before, since less margin of safety for equipment failures is required. In addition, a substantial saving in power is made.

In connection with regenerative features, each locomotive has generators geared to the axles of the pony trucks. These supply current to excite the main-motor fields during regeneration; at other times, while running, they supply current for the air-compressors. When this supply is not available the compressors take power from a small motor-generator set, or from the control storage battery. Thus a constant supply of compressed air is available at all times, whether the trolley is energized or not.

Due to the extremely cold weather common in the Rockies, train heating is of vital importance. To assure its independence of trolley-line conditions, each locomotive will carry an oil-fired steam boiler with storage tanks for 750 gallons of oil and 7,500 gallons of water.

Running gears and mechanical details for these locomotives will be furnished by the Baldwin Locomotive Works, and electrical equipment by the Westinghouse Electric and Manufacturing Company.

ONE of the chief points which Professor Edwards brought home to the users of high speed steel in a paper read before the Manchester Association of Engineers, was the importance of the temperature from which high-speed steels were hardened.

NO LET-UP IN ECONOMY

THERE is a grave danger that the passing of severe weather and the resumption of more or less normal railroading conditions will remove much of the seriousness of the coal situation from the minds of many of us, and that, as soon as personal discomfort is forgotten, the business of burning up coal will be continued with as much lack of attention as hitherto.

No language is strong enough to condemn those who waste fuel. That any man would actually take coal and dump it in the lake or otherwise dispose of it so that no one got any benefit is not to be thought of, yet that way of wasting fuel would be cheaper and easier than by installing expensive boilers and mechanical stokers and operating them carelessly.

Condemnation is doubly deserved when the waste involves wear and tear on plant and unnecessary exertion on the part of attendants.

Just as the finest automobile goes into the ditch when deprived of a guiding hand on the steering wheel, so can the efficiency of the finest plant disappear in smoke when uncontrolled.

An exact knowledge of what takes place in a boiler furnace is essential to every fireman. A due appreciation of this can only be had by investigating the composition of the waste gases and determining their relation to the furnace efficiency. Once furnace efficiency is understood, the heat transmitting features of the boiler demand attention, and this involves such items as clean boilers, inside and out, suitable draft to give the proper velocity to the gases, and sufficient load on the boiler to enable these conditions to be maintained.

The efficient use of all the various devices and apparatus for maintaining these conditions is part of a fireman's duties and places him above the old-time handy man who cared little whether he shovelled sand or coal.

It may be that the individual saving in any one plant is so small as not to appear worth while, but our actions to-day in respect of fuel are going to affect us ten or twelve months hence just as surely as the sun will rise to-morrow. It may not be possible for many of us to save a carload of coal over last year's consumption, but one more car on a freight train during weather like the past winter may mean the difference between breakdown of a locomotive and getting the coal through.

The total coal saved when the saving is good and the securing of supplies when opportunity offers are two ways of avoiding trouble next winter. They are not so commendable, however, as those methods which economize through increased efficiency, and every employer and every fireman, engineer and millwright should feel that his duty to the country, to the industry and to those dependent on him makes it incumbent to burn less coal and get more heat out of it whenever mechanical apparatus and devices make it possible.

HE READS THE ADVERTISING

HERE'S something to think about: "I never miss a chance to read the technical papers. I read the advertising pages and all. In fact I read the ads. first."

Now, that's not a saying that was hatched in the brain of a man trying to sell advertising matter for a technical paper.

It is the opinion of a steel mill superintendent, who entered the business as an apprentice in a machine shop.

From apprentice he went to journeyman, to foreman, to assistant master mechanic, to master mechanic and on to superintendent.

And all the time he has studied and read the technical and trade papers, and studied the advertisements.

It simply goes to show that the technical and trade press is filling a place in the life of the mechanic that no other paper can reach.

It keeps him in touch with the latest developments in a field that is constantly being changed by new devices that may make the fit plant of to-day obsolete in a few years from now.

The advertising pages of the technical and trade press are as up-to-date text books to the man who is coming toward the top.

Association and Personal

C. J. Hicks has been appointed assistant superintendent of the Dodge Mfg. Co. of Toronto. Mr. Hicks came from Midland, Ont., and previously to his work there has had wide experience in manufacturing work.

Adam Cook, the senior member of the firm of Adam Cook's Sons, manufacturers of Albany Grease, died on Feb. 19, at his residence, 148 West 78th street, New York City. Adam Cook was born in Albany, N.Y., in 1867.

R. A. Gurnham, who has been connected with the John McDougall Caledonia Iron Works for the past seven years, the last two as works superintendent, has accepted a position as mechanical engineer with Darling Bros., Montreal. He will be associated with the sales department.

Loyall A. Osborne, of New York, vice-president of the Westinghouse Electric & Mfg. Co., and chairman of the executive committee of the National Industrial Conference Board, has been appointed by the Secretary of Labor a member of a committee on industrial peace during the war.

E. A. Seath, formerly with the Montreal office of the Canada Wire and Cable Co., and the Moloney Electric Co. of Canada, has been appointed manager for the Maritime Provinces of these companies, and has opened an office at 674 Barrington Street, Halifax. He is succeeded in Montreal by Harry Riley, formerly of the Toronto office of the Canada Wire and Cable Co.

SWEDISH EXHIBITION

THE Swedish Export and Industry Exhibition has arranged a display of typical Swedish inventions for the purposes of interesting the public capitalists and exporters in the many practical and useful inventions to the credit of Sweden.

The exhibition will remain open for three months, and the exhibits numbering over 250 thoroughly cover the fields of industry and science.

A particularly interesting display showing the uses to which paper is being put shows entire costumes, gauze bandages, stockings, blind cords, machinery belts, towels, etc., all of paper.

NEW REGULATIONS FOR THE OPERATION OF STEAM BOILERS

AT the last session of the legislature of the province of Saskatchewan the boiler code was amended changing the system of collecting fees for the inspection of portable and traction engine boilers.

Owners of these boilers are now required to register them with the Department and to pay an annual license fee of $5.00 for each boiler.

On receipt of the above fee the Department will issue a number license plate which must be attached to the boiler, and after the 1st of January, 1918, no portable or traction engine may be used or operated which does not display thereon the numbered license plate for the current year as prescribed by the Act, under a penalty on summary conviction of not less than $10.00 and not more than $50.00.

Where the owner of a portable or traction boiler had already paid to the Department the annual fee for the current year the inspector will not charge any fee for the inspection of such boiler.

PEAT DEPOSITS IN CANADA

DR. EUGENE HAANEL, Director of the Mines Branch, has made a valuable report on the subject of peat, which is being given consideration in formulating a policy. Dr. Haanel estimates the total area of the Dominion overlain by peat bogs as 37,000 square miles, and of this total area the known peat bogs of Ontario, Quebec and Manitoba comprise 12,000 square miles, with an average depth of six feet. He estimates the 12,000 square miles will contain about 9,300,000 tons of peat, having a fuel value equivalent to about 5,400,000 tons of coal.

Seven bogs within convenient shipping distances of Toronto are estimated to be capable of producing approximately 26,500,000 tons of fuel; and seven bogs in the vicinity of Montreal could supply that city with 23,500,000 tons of fuel.

Five bogs along the Lower St. Lawrence, conveniently situated as regards water transportation to the City of Quebec, can, it is estimated, supply 16,250,000 tons of fuel and 5,700,000 tons of peat litter.

The bogs examined in Nova Scotia can produce 6,200,000 tons of fuel and 500,000 tons of peat litter, and those of Prince Edward Island produce 1,250,000 tons of fuel and over 1,000,000 tons of peat litter.

In Manitoba the aggregate fuel content of the bogs is estimated at less than 2,000,000 tons. One bog alone, however, it has been estimated, is capable of furnishing 2,500,000 tons of peat litter.

OPERATOR ORGANIZATIONS

British Columbia Association of Stationary Engineers, Vancouver.—Subordinate Lodges at Vancouver, Victoria, New Westminster, Cumberland, Merritt, and Fernie.

North-West Association of Stationary Engineers, Edmonton, Alta.

Manitoba Association of Stationary Engineers, Winnipeg.

Canadian Association of Stationary Engineers, Hamilton, Ont.—Subordinate Lodges at Montreal, Toronto, Hamilton, Ottawa, Brantford, Guelph, Kitchener, Chatham, Ont.; St. John, N.B.; Owen Sound, London, Stratford, Belleville, Kingston, Sudbury, St. Thomas, North Bay, Port Arthur, Sarnia, and Windsor, Ont. The executive officers of the C.A.S.E. Grand Lodge are as follows:—

Past President—W. G. Forbes, Montreal, Que.
President—R. F. Gofton, Kitchener, Ont.
Vice-President—Wm. Cooke, Belleville, Ont.
Treasurer.—A. W. Heath, Hamilton, Ont.
Conductor—S. Balmfirth, Toronto, Ont.
Doorkeeper—George Moll, London, Ont.
Secretary.—John H. Hale, Hamilton, Ont.

ELECTRICAL FITTINGS IN DEMAND IN AUSTRALIA

D. H. ROSS, Canadian Trade Commissioner in Australia reports that according to an authentic publication compiled in 1915 there were in that year 165 cities and towns in Australia lighted by electricity. Of the plants in operation 87 were municipally owned and controlled and 81 were private companies. Taken by states, Victoria had 75 cities and towns electrically lighted, New South Wales 42, Queensland 10, South Australia 7, Western Australia 22, and Tasmania 9. In one or two cities there are both municipal and private concerns furnishing light, the boundaries of the former being the city proper and the latter having as their sphere of operations the suburbs.

It is anticipated that the 1918 edition of the Australasian electrical directory will show a moderate increase in the number of towns which have adopted modern methods of lighting and also in power plants for manufacturing and tramway extensions. A number of contemplated municipal enterprises, in both lighting and power, have, perforce, been held in abeyance until the difficulties of increased expense of procuring the requisite material from overseas are less pronounced than at present.

For the time being imports are to a large extent restricted to parts and fittings necessary in ordinary extensions and in the maintenance of existing plants, though the volume of such imports is still very large.

The elimination of German goods, which constituted a large portion of the Australian purchases of electrical material abroad, has necessitated dealers seeking other sources of supply to make up the deficiency. The United States and Japan have been the principal gainers by these changed conditions, hence a like opportunity now exists for Canadian manufacturers.

The Operators' Point of View

THE STATUS OF THE ENGINEER

By James E. Noble

HOW that the question of graded certificates for stationary engineers has been shelved for awhile, it may not be out of place to give a personal opinion on the subject.

It is quite possible that I will bring up some of the points already discussed among the hundreds of articles which have been written about this matter; I will, however, also bring up one or two new items. As this article deals with my personal opinion it may be permissible to state that I passed an examination and secured a first-class certificate in the days of the Ontario Association.

However there are hundreds of fine fellows as good as the best of engineers, in practical operation, who are cursed with a mind which positively will not permit them to retain a vast amount of technical information in such shape as to be available on demand. These men have the knowledge in such form that they can solve the most difficult problems by using their text books to find the rules.

Unless a man understands the technical side of engineering the use of books at an examination would be practically useless to him. What I would suggest to the men who are boosting for a graded certificate is to embody in the law permission for the candidate to use text books at an examination for first class papers.

Did anyone ever hear of any engineer being asked to give the diameter of crank shaft required on a given engine, or to make a sketch of a properly braced boiler head, or to sketch a theoretical diagram (indicator) from an automatic cut-off engine, or to show the proper size pump required to supply a certain battery of boilers, or any one of a thousand such questions by any employer, without permission to refer to his text books? In operation I do not believe it has happened very often if ever, so why make the conditions on an examination different from those liable to occur in practice?

In a bookless examination on technical subjects, it is the man of the science school who is most liable to make a high percentage, while the practical self book educated engineer may fall down because his brain is full of original thoughts and practical knowledge and somewhat shy on rules.

I venture to state that most people could give a list of questions such as the examiners use in first-class examinations and a large percentage of the examiners would fail to make good.

This actually happened some years ago in one of the American states when the examiners themselves had to pass an examination such as they had been using, incidentally keeping many capable men out of first-class plants. It is all right to demand direct answers without the use of books to many practical problems liable to occur in any plant, and most of such questions should be used in the lower grade examinations. In the higher grade ones it is my opinion it would be the acme of common sense and common justice to allow the use of text books.

Before trying the examination for first-class papers I used up some months of valuable time memorizing hundreds of rules which were not necessary for me to know at the examination and for which I have had no use during the following twelve years, although first engineer in a power plant. The questions I was asked were all technical, which any man who had considerable book knowledge and no practical experience could answer. Of course, an applicant for examination is supposed to have some years' experience in a power plant, but I am thinking that the information given by the applicant himself is usually taken at its face value, and it is seldom that any engineer is asked to send or give proof that the statements given are correct.

It has been said that no system of education is in force that does not compel a man to learn a lot of things which will probably never be of any value to him. In engineers' examination for high-grade papers this rule need not be carried out. If the engineer reads his trade journal and text books, even casually, he will have, with the help of an index, a fair idea where to look for any information wanted. Information so found will be much more reliable than if the memory alone were depended upon.

A cipher placed in the wrong place may do a world of harm. With the memory this is quite possible; with the use of the best of the text books it is highly improbable. Therefore, why not allow the use of text books to answer purely technical questions at examinations?

Another idea is this: If a man has had a certain number of years' practical experience in full charge of a high pressure steam plant, and has a diploma from any good school (residential or correspondence) showing that he has completed a course of study in engineering, give this man a first-class certificate without further examination; he pays the regular fees, of course.

There are many of these men who have expended considerable sums of money educating themselves along engineering lines who possibly could not satisfy some pernickety examiner that they were qualified because their memory or mind is not a mass of useless rules and figures, but who are probably better engineers and safer men in a power plant than the examiner would be, and who could perhaps work out problems with the use of text books that would puzzle the examiner to answer with the use of the same books.

Call stationary engineering a profession if it suits you, but it will never be a profession so long as it is worked along the present lines.

Look at the civil or consulting engineer. He has no Government certificate. His college diploma and perhaps some practical experience is all he has, but he is considered as ranking in the professional class by the public at large. The power plant chief suffers very much by comparison in the eyes of the dear public.

Look at the places where compulsory examinations are in force. Is the engineer considered any more favorably by the public than in other places? No. In order to better the condition of the stationary engineer we must persuade the Government to pass a law making it compulsory for first-grade engineers to have a certain amount of practical experience and a college or correspondence school diploma for a course in steam engineering, and see how soon the stationary engineer will rank with the civil engineers.

We must get some modern thought into the system; never mind the old chestnut of compulsory examination by the memory test. Get permission from the Government to allow such first-class engineers only to use the letters S.E. after the name, and see how soon the public will sit up and take notice. The stationary engineers will then have a place in the sun. How many people outside of the engineers themselves and a few of their employees know that there is such a thing as a Government examination? The employers who were notified about the matter have now forgotten it. As the Government is beginning to enforce the law, some more employers will hear about it, but they will soon forget it again.

If it is better remuneration the engineers want, the scheme outlined above will help out. If it is glory, it also holds good. If it is for love of the public only and the desire to supply good men to good plants, the scheme is a top-notcher.

OXYGEN AND PERPETUAL MOTION

IN the February issue of POWER HOUSE, on page 46, there is an article telling of an invention of a Mr. Gallagher for obtaining oxygen from the air with no other expense than the first cost. So far so good, but your correspondent goes on to say that the inventor is perfecting (I believe that is the term used) the invention, and is experimenting on an internal combustion engine, in which the oxygen obtained from the air is to take the place of oil, gas, or gasoline.

Mr. Editor, that would surely be some engine, if your correspondent is right.

As far as my memory serves me I learned that oxygen is incombustible, after the manner of some of this winter's coal; that is the only fault I have to find with the invention as reported.

If oxygen can be manufactured free of cost (practically speaking) the inventor will have conferred a boon upon all long suffering engineers. Perfect combustion without excess air, just what all engineers, and incidentally owners, have been looking for.

In an internal combustion engine, too, it would certainly help wonderfully. About 4 or 5 times the power could be developed in an engine of the same size, as one in which air is used to support combustion.

But as for taking the place of oil, etc., I 'hae my doots'.

I am afraid it looks too much like a perpetual motion machine. There have been so many revolutionary machines and engines that somehow failed to revolute. However, I await confirmation of the report with great interest.

Toronto.

A CHART FOR FINDING THE LENGTH OF COILED PIPE, ETC.

By N. G. Near.

WITH the aid of the acompanying chart it is a simple matter to determine the length of a coil of rope, the length of a pipe so familiar to the plumber, the length fo a coil of rope, the length of a coil of wire, or a coil of almost anything as a matter of fact. This chart, however, was made primarily for pipe. The size limits of this chart, it will be noted, range from 4 to 30 inches in diameter (column A) and from one to 60 turns (column C). This limits the charts to a bit over 400 feet.

To use the chart, measure the "average" diameter of the coils as indicated by the sketch on the chart itself. That is, measure from the "mid-point" of one side to the mid-point of the other side in inches. Then count the number of coils. Then connect the diameter (column A) with the number of turns (column C) and the intersection with column B immediately gives the total length in feet.

For example. What is the approximate length in feet where the diameter is 15 inches and the number of turns is 20?

Connect the 15 (column A) with the 20 (column C), as indicated by means of the dotted line drawn across the chart and the intersection with column B immediately shows the length of the coil of lead pipe or whatever else it might be as very close to 79 feet.

It is evident that it is much quicker to use this chart than to unroll the pipe and measure it, or even to compute it, knowing that to compute one must divide the diameter in inches by 12 and multiply by 3.1416 and then by the number of turns in arriving at the result. Besides, this method is just as accurate anyway because of the judgment that must be used in measuring the diameter.

This method is much quicker and easier than to unroll a long coil and measure it with infinite care and then roll it up again. The method is not "absolutely accurate" but for most rough purposes it will do very well indeed. If it is desired to determine the "exact" length within an inch or even a foot (provided the coils are large) there is no surer method than unrolling and measuring in the longhand way. But if the answer is wanted only approximately, why do it the hard way?

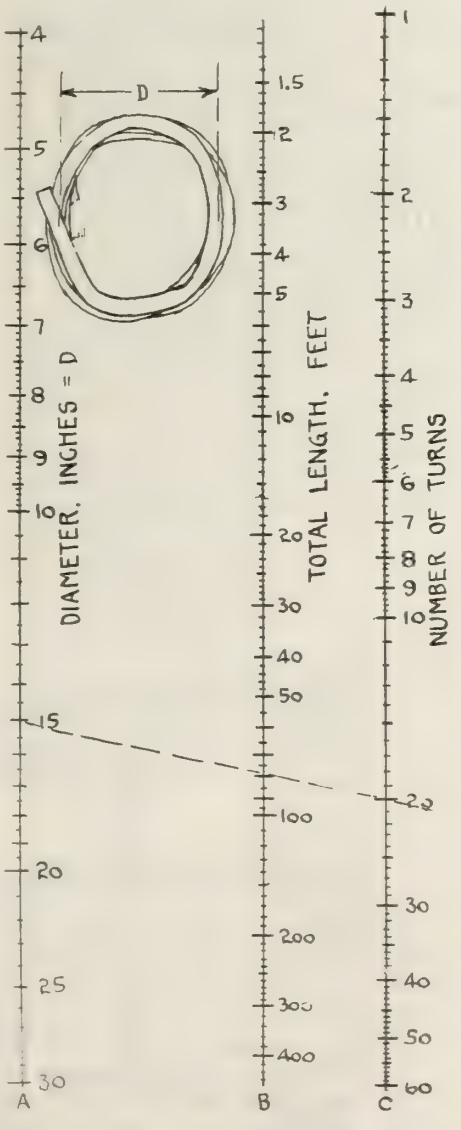

CHART FOR DETERMINING THE LENGTH OF COILED PIPE, ETC.

SETTING MACHINE TOOLS

By D. S. Mann

WHERE machine tools are placed on concrete floors as they are ,in the greater number of cases, it is quite a job to put

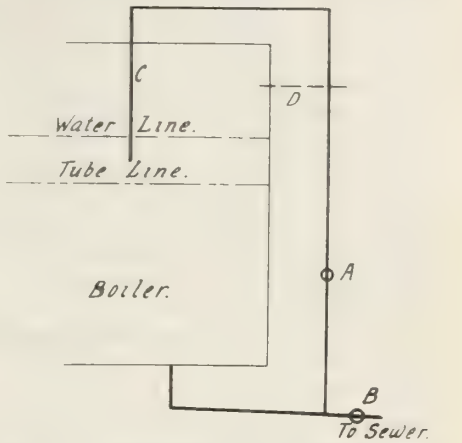

FIG. 2. ALTERNATING ARRANGEMENT OF BLOW-OFF PIPES

in the foundation bolts for holding same. Of course, for the larger and more weighty machine no fastening is necessary, and especially so if motor-driven. However, the average machine tool will finally work its way out of position either from the belt pull or by being struck with trucks or heavy castings. Several years ago the writer installed the machines in a manufacturing shop and, not being quite certain as to their ultimate positions, adopted the following plan:—The machines were levelled up by means of iron wedges and raised about three-quarters of an inch off the floor. A good strong mixture of sand and cement was mixed up with a generous supply of fine iron chips. This was worked wel under the edge of the machine so as to have a good wide bearing and was extended out about one inch, giving a bevelled edge entirely around the machine. When this hardened it seemed impossible for the machine to move and, to the writer's recollection, none ever did move. Adding the iron chips formed a very hard cement, and even where castings were rolled against this edge it seemed almost impossible to crack it. If it were desired to move the machine it could, of course, be ervy easily raised and the cement band then broken up.

ASKED as to the occupations of national importance which were available for discharged disabled men, Sir A. Geddes said, on the 31st ult., that they were: Shipbuilding, ship repairing, marine engineering, munitions, agriculture, agricultural implement making, food production, railways, tramways, iron ore mines, gas, water and electric undertakings.

CIRCULATING PIPES

By James E. Noble

MANY blow-off pipes are connected to steam boilers with no circulating or equalizing pipe; this is a serious mistake as it is quite possible for steam to form in a pipe so connected, with the result that the water is forced out of the blow-off pipe into the boiler, allowing the pipe to become overheated, and, if the water rushes back into the overheated pipe, it is quite possible that a fracture may occur, caused by rapid contraction. Some engineers advocate connecting a circulating pipe at the water line of the boiler; the main objection to this is that the circulating water will act as a surface skimmer, to some extent depositing the impurities inside the boiler near the blow-off. If the blow-off is used often no harm would develop, even if the water was pretty dirty, but the objection can be overcome by using a double connection as shown in Fig. 1. To use the surface blow-off close valves A and C and open B and D. When not using the surface blow-off close B and D and open the other two. The funnel piece G should be made from sheet copper; a pipe coupling is soldered on to the end and this in turn is screwed loosely on to the end of the 1¼ inch pipe coming through the tube end of the boiler.

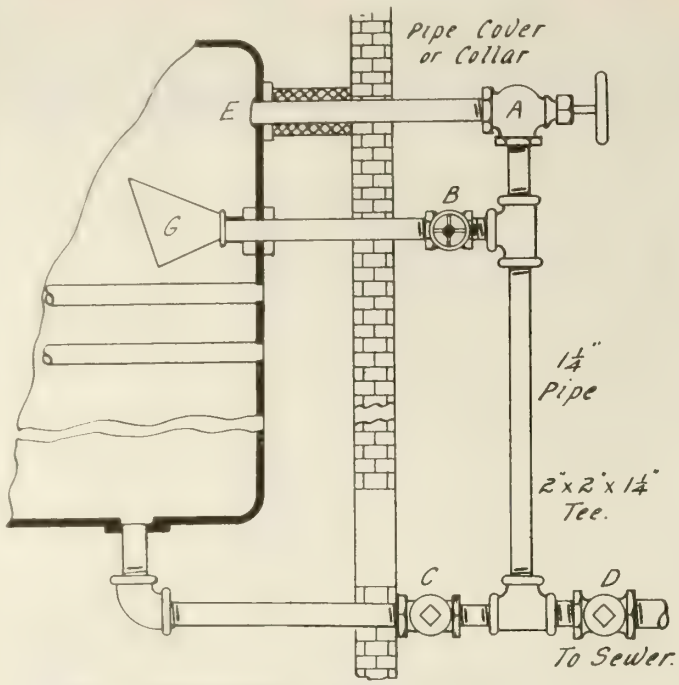

FIG. 1. ARRANGEMENT OF CIRCULATING BLOW-OFF CONNECTIONS.

When cleaning scale from the back head, the funnel can be unscrewed by hand and placed aside out of the way until ready to close up the boiler, when it can be replaced. Objection may be made that there are too many valves to operate in this outfit. Eliminating the skimmer, the circulating pipe can be installed as indicated in the diagram, Fig. 2, page 79. To blow-off close valve A and open B. When not using the blow-off, B is closed and A left open. The circulating pipe will work even if the pipe C does not go below the water line, although experiment seems to prove that connected as shown in the diagram, better results have been attained. Unless the pipe is connected below the water line it is better to run it up outside the brickwork and connect it into the top of the boiler as shown in Fig. 2. If it enters the head of the boiler, at the steam space, it is liable to get burned at part shown by the dotted line D, Fig. 2.

AN OIL FILTER

By John Port

SO many oil filters have been described that I hesitate to describe another. The one here shown has proved very satisfactory in operation and has many advantages over a number of home-made filters in operation to-day.

The tanks made from galvanized iron can be obtained from any tinsmith for a few dollars and the taps and pipes can be installed by any operating engineer. The filter can be made any size according to the size of the plant. So far as cleaning dynamo or engine oil is concerned the filter will work like a charm just as shown.

If it is desired to filter lard oil, cylinder oil or any other heavy oil it will be necessary to instal a steam pipe in the compartment B, below the waste, to keep the oil thinned.

One feature should be noted in the design of this filter, all pipe-work in the various sections should preferably be of the same size and ½ in. galvanized iron pipe has been found satisfactory in this respect.

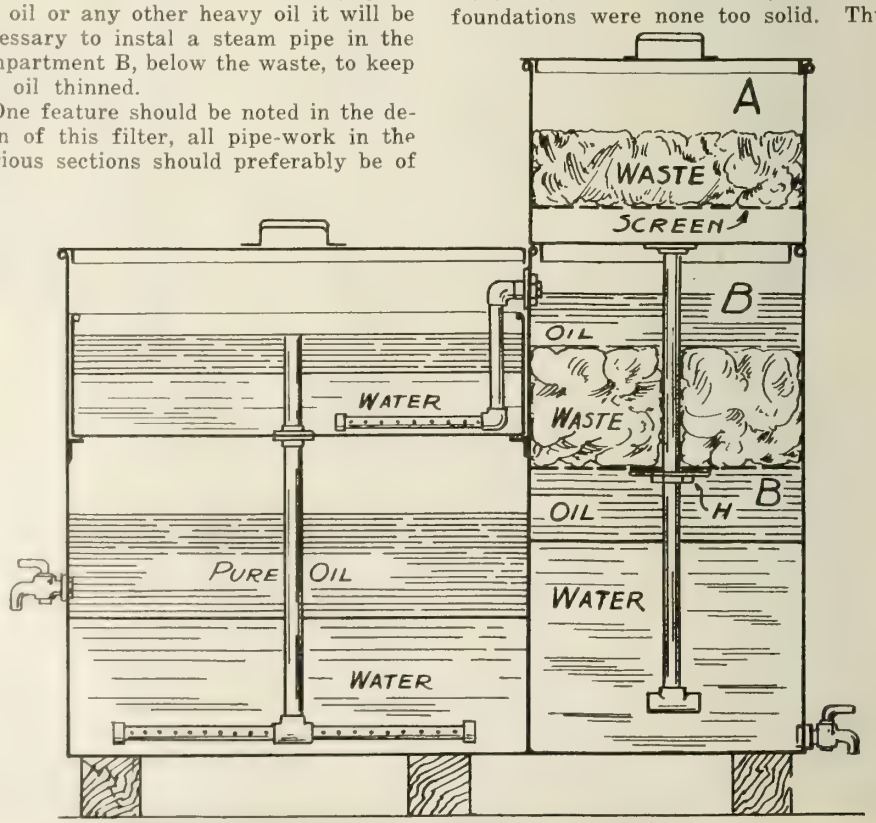
The oil to be filtered is put into tank A, passes to the bottom of tank B, up through the waste and into tank C, and from there through the water to tank D, where it passes out of the tap E.

There is a coupling and a large iron washer at H; this holds up the perforated iron screen. Tank A acts as a cover for B and lifts out, taking the screen pipe and waste from B when cleaning is required. By removing the locknut at K the pipe can be removed and the tank C lifted out for cleaning tank D.

When cleaning out the tanks any oil therein should be saved and refiltered.

It is quite safe to use oil filtered with this machine as very little oil will get past tanks A and B. These two last-named tanks will require cleaning more frequently than C and D.

This filter will do as good work as many manufactured at four times its cost.



SECTION THROUGH FILTER SHOWING ARRANGEMENT.

THE JOYS OF A MILLWRIGHT

By D. Middleton

THE Milo mill of the United Paper and Pulp Co. was a sort of dumping ground for the machinery that had outlived its usefulness in the company's other plants. And yet they were supposed to, and did, turn out the finest grade of tissue paper —which was a silent tribute to the men who would put up with such conditions and made a go of things discouraging.

Machinery of this class is heavy and is subjected to all sorts of sudden strains and unfavorable conditions in the way of location and dampness. The buildings of this plant were all of wood, the floors were wet most of the time, and the foundations were none too solid. Thus

it was that shafting got out of line about every so often, and if it wasn't discovered in time the word would come that "the 4½ in. shaft in the beater room just broke close up to the hanger by the driving pulley." That being the only piece of that size on hand, and the orders being to get no new material where old could be used, it was up to the shop crew to shift the remaining length of 4½ in. along and splice out the gap with a piece of 4 in. or 5 in., whichever could be found out in the yard. Often this meant changing a couple of old-fashioned hangers that seemed to weigh a ton to the boys working up against the damp ceiling, and always it meant filling up one or more of the numerous keyseats in the shaft so they could run in the hangers at that spot. And then new keyways had to be cut by hand. The job had to be done at once, and there was no rest for the crew until it was finished.

Fitting Keys

The showing that the plant made was due in no slight measure to Frank Maclay, the machinist, who would have done even better if there hadn't always been three months' work ahead of him which he had "to keep him busy," and to work on when something wasn't actually breaking. Maclay was the best man on fitting up keys that the writer has ever known, and it is from the experience gained while working with him that the writer has always since been able to guarantee a job of this kind that had been done according to instructions. Surely Maclay was right, for I never knew a pulley or gear in that plant to come loose—and the drives were of the hardest—and it gave one a sick feeling to be told to take a pulley or gear off a shaft that he had once keyed up. Some of Maclay's key maxims were: "I never expect to see a gear stay tight if it doesn't fit the shaft; if you want me to put it up, I'm going to bore it out and put in a sleeve that will fit.

"I don't want any key put in that doesn't bear all around, top and bottom and sides; if it's going to drive more than two dog power, it won't last if fitted any other way. Make a long enough head on your keys so the driving don't swell the key proper.

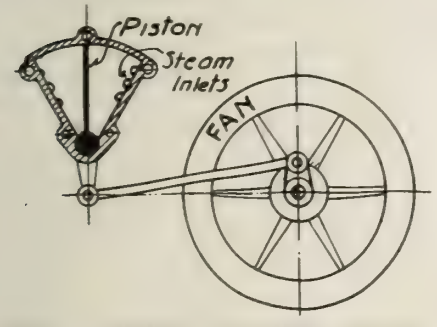


FIG. 1. PRINCIPLE OF NOVEL ENGINE.

"Your hammer ought to weigh about two pounds to the inch (that is, a 2 lb. hammer on a 1 in. shaft, a 4 lb. hammer on a 2 in. shaft, etc).

"If you're going to expect a key to stay in a shaft or hub. you've got to drive it home with something besides a chipping hammer. If the hub is too light to stand that without cracking it is going to give you trouble sooner or later anyway.

"I don't want any keys with a taper on them of more than a thirty-second in four inches—give a man a taper key and he depends on that for a fit every time—thinks because he drives the key till it stops it is fitted; if he makes that kind of a job tight he splits the hub at the top of the keyseat. When you are fitting keys by driving and trying and filing, use twice as heavy a hammer for driving out as for driving in—if you do that you won't get the point end all swelled up. A heavy hammer drives, it does not swell locally. Put oil, just a little, all over a key every time you drive it in a hole, and you won't have stuck keys.

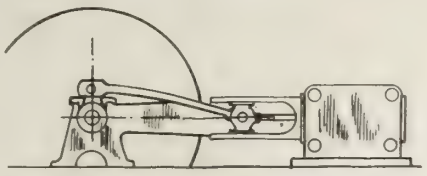

FIG. 2. BENT CONNECTING ROD ON CORLISS ENGINE.

"The smoother your keyway faces are the tighter you key will be; a rough side on a keyway will impress its roughness in the key and may go so far as to loosen up the fit. Take time enough to fit your key all over for the full length—do that, get a tight fit, and you won't have to be doing the job over again every second Sunday. Make your key long enough so that you can drive it in further and tighter in about a week if the key is subject to a pull both ways or from light to full load and the strain is a heavy one."

Unique Steam Engine

Supplementing the water power at this paper mill were several engines, rejected at other plants but doing fair service at Milo. One of these, Fig. 1, was a curiosity, to me at least. It had a "cylinder" of triangular shape, apex down. In this cylinder a piston-like fan oscillated on the shaft at the bottom. The valve admitted steam alternately on the sides of this piston, and the movement was transmitted by an arm outside the cylinder, through a connecting rod to the crank. They had shut down this engine at the time I was there—said it wasted too much steam. Another of the antiques had the cross-head guides made of wood; they were worn just as smooth as glass, and certainly presented a fine surface.

The best engine of the bunch was the 300 h.p. Corliss, on which a never-to-be-forgotten job was done. In shutting down for supper one night the engineer forgot to open the cocks—a fatal mistake, as the steam came a hundred and fifty feet through uncovered pipes. The back stroke caught the water and the connecting rod—of wrought iron—buckled, Fig. 2. On the forward stroke the rod failed to straighten out entirely when the cylinder head was reached, and the momentum of the flywheel crushed the key in the crank and everything stopped dead, for the key did not shear off. That was some key, and it was my job to get it out.

After two days of drilling with a ratchet, we were able to drive the key loose and get the crank off. The latter was sent to a shop in the nearest town to have the keyseat squared out and a key made. I started with hammer and chisel to re-cut the shaft end. By the time the crushed portions had been dressed up, a 2 in. x 3 in. key was needed—originally it had been about an inch less each way. Every inch of the fifteen-inch length of the shaft meant another blister for the fortunate chipper, and on top of that "old Moran," the superintendent, insisted on having a 1½ in. key put in at right angles to the other one to make the job doubly secure. And one afternoon he brought in a friend who said he could show us a way to cut the keyways in a jiffy. He suggested using a dentist's drill and boring the metal away. I told him steel was tougher than teeth, and old Moran looked at the 3 x 15 of steel and the husky pile of chips on the floor and suddenly thought of something in the office he needed, leaving me and dragging the dentist with him.

The forge was out in the barn, up the lane, and it was necessary to wade through the snow to go there and draw out the chisels. A diamond point was used to cut the path at the edge, then the center was readily cut out with a flat chisel without breaking the corners. A cape chisel and files were used to straighten up the sides and the bottom.

When the new keys came from the shop, they were found to be two inches too long. We had no power saw, so they were chucked in the lathe and reduced with a cutting-off tool. The keys were fitted in good shape and finally driven home with a twenty pound sledge. We left a half inch—all that would clear the rod—projecting, and the Sunday following the starting up we managed to drive that all the way in. That was fifteen years ago, Maclay and old Moran are both dead, but the keys go driving on, and have never needed attention.

That lathe was a 20 in. affair that served the plant as lathe, shaper and drill press. An extension had been added at one time that allowed it to take 15 feet between centers. Somehow they managed to do a job on it that would pass, but when it came to turning the work that was over the extension, the lathe hand had to feed by hand for the screw had not been lengthened. A sharp watch had to kept of the size, too, when using the extension, to offset the persistent taper produced by the sagging back end. In the spring when the brook was high, the legs were awash, and the lathe man had to wear boots. In spite of these handicaps, all the lathe work of the shop was done here; it had to be, in fact, for Moran wouldn't give an order for any outside work "with a good machine out there standing idle."

ALCOHOL AS A MOTOR FUEL

By J. E. MacCormick

THE appearance in these columns recently of articles dealing with the subject of industrial alcohol has caused the writer to investigate the subject at some length, and the following remarks and statements are submitted for the approval or otherwise of readers. I have noticed that some periodicals have recently inserted articles intimating that distillery men should now turn their attention to the production of a grade of alcohol suitable for motor fuel. It looks to me as though if encouraged this could develop into another alcohol versus gasoline agitation such as swept over America about a dozen years ago, and became so marked that during 1906-1907 the United States Congress passed certain acts intended to especially favor "distillers producing alcohol from any substance whatever for denaturation only, and having a daily spirit producing capacity not exceeding 100 proof gallons."

How this worked out is intimated in Chemical Bulletin No. 130. Bureau of Chemistry, U. S. Department of Agriculture. I quote from page 9:

"Therefore, in 1907 it was provided, by an amendment to the original Act, that especial encouragement might be given by the Commission of Internal Revenue to distilleries producing industrial alcohol in amounts less than 100 proof gallons daily by the removal of many of the restrictions which are imposed on larger distilleries and on those in which potable alcohol is produced.

"It was believed that as a result of this action it would be possible for farmers to make crude alcohol at so low a cost that they could utilize it advantageously upon their farms as a source of power, light, and heat; and it was expected that many communities would establish such agricultural distilleries as were contemplated in the Act. Over a year passed, however, without any attempts to make alcohol upon this plan, to the serious disappointment of all who were interested in the matter, and it became apparent that further encouragement was needed.

"By numerous misleading publications a great many people had been led to believe that any waste vegetable material, though of the most worthless character, can profitably be used in making alcohol. Evidently it was necessary to teach the community which types of material can be so used and which can not. They had also been led to believe that the apparatus of a small distillery can be built very inexpensively, and that the manufacturing process is very simple. Evidently it was necessary to furnish accurate information regarding the cost and construction of small plants and regarding the processes of mashing, fermenting, and distilling."

From the "letter of transmittal" on page 3 of the above bulletin I quote: "Although now almost three years have elapsed since the passage of the Act permitting the use of industrial alcohol free of tax, not a single agricultural distillery has yet been successfully established." This letter was dated August 7, 1909.

In those times one of my hobbies was that the gasoline motor was the proper automobile power plant; another was that the gasoline tractor was the coming farm power. Then the above-mentioned gasoline versus alcohol agitation led me to believe that the alcohol engine would finally supersede the gasoline engine. Then the chance remark of a friend that "one could not use the refuse from an auto for fertilizing purposes as could be done with that of the horse" influenced me. I believed the thing could be done, for I remembered the story of the farmers of "ye olde times" who found distillery refuse an excellent fertilizer. My interest in the alcohol problem being thus intensified, I procured reliable literature on the subject and spent my evenings reading up on the matter. The result was that I abandoned the alcohol as a motor fuel proposition as being so expensive as to render it commercially impracticable. I will now try to give a brief sketch involving some outstanding features.

Cost not considered, the alcohol is more pleasant to use, and as regards fire and explosions, it is less dangerous than gasoline. As to efficiency and fuel consumption, when alcohol was used in engines designed for gasoline and the engine operated on each fuel separately for a time the proportion of alcohol used to gasoline used for equal power obtained varied from 1.3 to 1.8 gallons of alcohol as compared with 1 gallon of gasoline. The average was 1.6 to 1. With the alcohol burned in an especially designed engine (having a compression of 180 lbs. above atmosphere) the proportion was reduced to 1.2 to 1, and it was believed possible to improve the design to a point where, when each fuel was used in its own type of engine, the h.p. hrs. obtained per gallon from each of these fuels would be about equal. Changing a gasoline engine over (to use alcohol) by merely boring out the carbureter need not affect the consumption of gasoline, but the consumption of alcohol would be 1½ to 2 times that of gasoline for the same power. Victor W. Page in his book, "The Modern Gasoline Automobile," 1913 edition, page 235. says: "An engine designed for gasoline will use twice as much alcohol as it does gasoline to develop the same amount of energy, though in a special motor the same amount of power will be obtained as when equal quantities of gasoline are burned in the conventional engine. One of the disadvantages of alcohol that is shared in common with kerosene is that it is difficult to start an engine when cold, as alcohol is not very volatile unless heated." On page 236 he tells how to start an alcohol engine by passing the vapor through calcium carbide, the water present in the alcohol thus forming acetylene gas which, being very inflammable, increases the explosive value of the alcohol vapor.

Bulletin 93 of the Iowa State College of Agriculture, in its summary says:—

4. Alcohol of 94 per cent. purity must be sold for from 11 to 17 cents per gallon to compete with gasoline for lighting purposes at 20 cents per gallon (the present retail price of gasoline in Ames). (July, 1907.)

8. To compete with gasoline at 20 cents per gallon for use in gasoline engines 94 per cent. alcohol must be sold for from 13 to 17 cents per gallon, and 90 per cent. alcohol from 11 to 15 cents per gallon.

9. None of the engines could be started readily with alcohol, although a few could be started with less difficulty than others.

13. Gasoline can not be used readily in a special designed alcohol engine using high compression on account of preignition.

United States Department of Agriculture Bulletin No. 277 in its "conclusions" says:

18. By reason of its greater safety and its adaptability to the work alcohol should immediately supplant gasoline for use in boats.

20. In most localities it is unlikely that alcohol power will be as cheap as gasoline power for some time to come.

With regard to the use of alcohol as a source of heat, Bulletin 429, page 31, says: "Such data as are at hand indicate that the coal consumption—per gallon of 180° alcohol produced—may vary from 11 pounds under the most favorable conditions to 38 pounds in a poorly equipped and poorly managed plant. As 11 pounds of coal as a distillery fuel yield almost 159,000 heat units and a gallon of alcohol gives about 75,000, it is apparent that the use of alcohol so produced for heating would involve a great waste and he altogether unprofitable."

In connection with the economic phase of the use of alcohol as a motor fuel the above statement is very significant.

On page 32 the above bulletin says: "The alluring statements sometimes made regarding large financial returns to be obtained by making industrial alcohole with waste raw material, unskilled labor, and a 'cheap' distillery outfit, are misleading, and can only result in loss if followed."

It will be noticed that this is speaking of alcohol production from waste materials. Most of these rules also hold good in production from materials of more or less market value.

With regard to alcohol production, Bulletin 410, page 6, says: "One per cent. of sugar or starch in a product will produce approximately one-half of 1 per cent. of alcohol. It is not practicable to distil a fermented solution containing less than 2 or 3 per cent. alcohol. It is, therefore, evident that materials containing less than 6 per cent. of sugar or starch cannot be considered suitable for the profitable manufacture of alcohol. . . . The next point to be considered after it is decided that the raw material to be used contains sufficient sugar or starch is the supply of this material and the cost of its delivery to the distillery. Further, there must be available a good supply of water for the condensing apparatus and cheap fuel for the boilers. All of these considerations must be carefully weighed before any attempt is

made to establish a distillery. The detailed discussion which is to follow regarding the location, equipment, and operation of a potato distillery is applicable, in a general way, to the handling of other waste materials of the farm, and will be valuable as indicating the conditions under which such materials may be successfully used."

McPherson and Hendersons' course in general chemistry tells how dextrose may be obtained from starch, and, speaking of ethyl (grain) alcohol, says: "It is prepared by the action of ordinary brewers' yeast upon certain sugars, especially maltrose and dextrose. With dextrose the reaction is shown by the following equation:—$C_6 H_{12} O_6 = 2 C_2 H_5 O H + 2 CO_2$."

Bulletin 429, pages 21, 22, says:—"The chemical composition of dextrose, which is the form of sugar occurring in most ripe fruits, is represented by the formula $C_6 H_{12} O_6$, which signifies that one molecule or unit of the compound substance dextrose is made up of six atoms or units of the element carbon, twelve of the element hydrogen, and six of the element oxygen. When fermentation takes place the molecule of dextrose breaks up substantially, as is indicated by the following equation:—$C_6 H_{12} O_6 = 2 C_2 H_5 O H + 2 C O_2$.

This signifies that after fermentation is over the dextrose will have disappeared, and in its place will be found an amount of alcohol containing all of the hydrogen, two-thirds of the carbon, and one-third of the oxygen of the sugar, and an amount of carbon dioxide containing one-third of its carbon and two-thirds of its oxygen. Theoretically the total weights of the alcohol and carbon dioxide which are produced in the fermentation should equal exactly the weight of dextrose which is decomposed, and 100 pounds of the sugar should yield 51.11 pounds of alcohol and 48.89 pounds of carbon dioxide.

In practice, however, the decomposition is never complete, nor is it ever so simple as is indicated by the foregoing equation. Only in carefully conducted laboratory work is it ever possible to ferment any sugar completely, and even then, as a result of life processes of the yeast which are not yet understood by chemists or biologists, small and varying proportions of the sugar escape transformation into alcohol, and are converted instead into other substances. According to the investigations of Pastuer, 100 pounds of dextrose, instead of yielding the theoretical weights of alcohol and carbonic acid indicated by the equation, will produce in laboratory practice the following amounts of fermentation products:

Alcohol	48.55	pounds.
Carbon dioxide	46.74	„
Glycerine	3.23	„
Organic acids	.62	„
Miscellaneous	1.23	„
Total	100.37	„

The fact that the total weight of the fermentation products exceeds slightly the weight of sugar fermented is explained on the ground that the formation of certain of the by-products is accompanied by the absorption and fixation of slight amounts of water.

In manufacturing work such completeness of fermentation may be taken as an ideal toward which one is to strive. According to the skill of the distiller, the character of his mechanical equipment, and the quality of his water, yeast, and fermentable materials, his yields of alcohol may approximate those indicated, or may, on the other hand, fall far below it.

The above-mentioned facts in regard to there being evolved nearly as much weight of carbon dioxide as of alcohol is significant. It is for the purpose of allowing this dioxide to escape that, except where other means are provided, three-inch or four-inch holes are sometimes cut in the distillery vat room floor. In fact, during the process of manufacturing a gallon of alcohol we actually throw away—allow to go entirely to waste—at least one-half as much carbon as the resultant alcohol itself contains, and not only that, but in proportion to the efficiency of our plant we burn from 11 to 38 pounds of coal in the attempt. (See above extract from Bulletin 429 with regard to fuel required.) This looks very like an unwarranted wastefulness when it comes to manufacturing alcohol for fuel purposes, especially in instances when the escaping carbon dioxide is the result of the decomposition of dextrose obtained from a substance which could otherwise have been profitably used for foood purposes; and the coal is not really too plentiful either.

TABLE No. 1.

Name of Material—	Pounds required
Shelled maize	20
Barley	21
Wheat	22
Rye	24
Oats	29
Sweet potatoes	53
Potatoes	69
Sugar beets	84
Corn stalks (theoretically)	285

I have made calculations on a number of raw materials with a view to ascertaining how many pounds of raw material were required to produce a gallon of 90 per cent. alcohol. The data on which I based my calculations were obtained from different sources, and did not always mutually agree. When authorities differed I chose the one allowing a gallon from the smallest number of pounds of raw material. By this means I obtained the following tabulation, the figures being the number of pounds of raw material required to obtain one gallone of 90 per cent. (180° proof) alcohol. It must be remembered that the authorities being American, the alcohol will be in American gallons (231 cu. in. per gal.).

From a record of engine tests made in the Iowa Agricultural College at Ames I calculated that the eight horse-power engine designated as No. 1 and developing 8.6 b.h.p. (which was more economical than the lighter load) would in 2,100 hours (approximately ten hours a day for eight months) consume 3,864.8 (practically 3,900) gallons of alcohol. With motors especially designed for alcohol this amount would about nicely suffice for one of the twelve horse-power size operating for a similar length of time. From tabulation No. 1 I calculated that the amount of raw material required to provide the 3,900 gallons are approximately:

TABLE No. 2.

Either	Maize	1,393	bush. of	56	lbs. per bu.
or	Barley	1,706	" "	48	" "
or	Wheat	1,430	" "	60	" "
or	Oats	3,326	" "	34	" "
or	Potatoes	1,483	" "	60	" "
or	Sugar beets...	164	tons		

To this must be added at least this minimum of $3,900 \times 11 = 42,900$ pounds of coal, together with a share in the overhead charges of the plant.

The result of this expenditure is the obtaining of a supply of alcohol sufficient to operate an alcohol engine of about 12 b.h.p. ten hours a day for eight months. Economical do you think? Of course, if I had taken the less favorable data the above quantities of raw material would have been materially increased, but even these figures point out that to secure appreciable quantities of alcohol for motor fuel would entail the cultivation of extensive areas of farm land for this purpose alone. In fact, with the exception of artichokes and sugar beets, the prospect looks discouraging, does it not? The reason for favoring artichokes rather than potatoes is that they are reported to give a much larger yield per acre

EFFICIENCY OF PAINTED RADIATORS

THE practice of painting radiators with various metallic paints is not conducive to economy according to recent tests carried out at the University of Michigan. In comparing the heating effects of radiators not painted and those painted with bronze, aluminum, lead paint, Japan and enamel, it was found that radiators not painted and those painted with lead paint, Japan and enamel had about the same heating effect but the radiators covered with the bronze and the aluminum paints had about twenty-five per cent. less heating effect. That is, the aluminum and the bronze paint reduced the amount of heat that the radiator could give off. It was also found that it is the last coat of paint that increases the radiation, so that if bronze paint is put on over the other paint the heating effect is reduced one-fourth, while if bronze paint is covered with the other paint then the heating effect of the radiator is brought up to normal.

If a radiator covered with bronze paint is not heating a room sufficiently, covering with lead paint, Japan or enamel will increase its heating effect one-fourth to one-third, or will be equivalent to increasing the heating surface one-third to one-fourth, or it will make three radiators give off about as much heat as four radiators covered with bronze or aluminum.

THE SOURCE OF ENERGY

By Paul Raiko

JUST open any good newspaper on any old morning and you will see that the most poignant question about and most imperative need is of coal, wood or gasoline, any kind of fuel wherefrom a good amount of energy could be produced.

The energy is badly wanted to keep the wheels of the factories in motion, the trains running, the bread baked, the streets and houses lighted and, above all, the dwellings heated. Most rigid economy of fuel, mainly that of coal, is painfully enforced.

Much of coal is burnt to generate compressed air. Ask the railway authority, how many tons of coal is burned daily to have sufficient amount of proper pressure of compressed air to run all their turn-tables, pneumatic hammers, forges, furnaces, etc. Compressed air is decidedly a good form of motive-power, as good as steam and many mechanical engineers are of opinion that compressed air is even better than steam for quite a number of reasons: Firstly, it is healthier for all parts of machinery—the cylinders, the pistons, the stays, etc., because the temperature of compressed air is even, free from contrast of extreme heat and extreme cold, which causes the machinery to expand and contract and some parts of machinery to burst and break. Compressed air is practically free from such an accusation.

If a certain amount of compressed air is wanted, is it really so necessary to burn coal for it? Decidedly no. Why not try to find another sourec of energy to generate and store compressed air? Is there not another source? Look around; better, What is the wind?

To construct so many standardized windmills that would keep in motion as many standardized air-compressors would undoubtedly supply a city, or a community, or even country with a considerably good energy and it would undoubtedly pay.

A box-car full of good soft coal at $4 a ton costs about $100. How much will an old-fashioned Dutch windmill of four wings cost? How much costs an air compressor of the size and capacity of a standard air compressor which is attached to a standard railway locomotive? The price of these two features will not much exceed the cost of a carload of of coal.

But four wings and an air compressor can serve and work very long, practically permanently, and will require few repairs. Now, suppose a number of air compressors compress air into a tank, or a battery of tanks. This compressed air will turn an air-engine and a dynamo and produce electricity free from expenses on fuel. If such a plant is provided with reserve tanks and a storage battery, then the supply of power can be uninterrupted. The light as well as power would be supplied at a cheaper rate, and it would pay.

It may seem to some persons a dream. But well, most of the inventors were considered dreamers at one time or another. Yet I do not claim this my idea an invention. Just a wit, forced, perhaps, by the shortage of coal and suffering from cold.

If there was a sufficient supply of electricity, this wonderful energy could be used for cooking and heating purposes. It is not absolutely necessary to ask a big professor for the advice. Ask a machinist, a railway engineer or fireman, or a machine-shop help.

Once I asked a good fellow, a school teacher, how much motive-power could be produced from wind alone.

And the power which can be derived from the wind alone my friend has defined with a single word: **Limitless.**

SALVAGE OF GREASE AND OILS FROM BRITISH MOTOR VEHICLES

THE grease removed in the cleaning of wheels, axles, and other parts of motor omnibuses, trucks, and other motor vehicles, is now utilized by the London General Omnibus Co., London, England. The process of reclaiming the oil is thus described in the *Commercial Motor*.

Before the war kerosene was largely employed for the cleansing of engines and other parts of vehicles, but now its consumption is restricted to the barest minimum, the net effect being the saving of five-sixths of the former consumption. Kerosene, as a matter of fact, is now only employed on certain parts of the mechanism for the cleaning of which there is no practical substitute. For the cleaning of wheels, axle casings, and front axles, a weak solution of hot caustic soda is employed.

When engines, gear boxes, back axles, or any other parts are stripped for overhaul, a very great saving is effected over former practice.

Process of Reclaiming

The unit is dismantled and the parts are placed in a cradle and dumped into a tank of water into which a jet of steam is turned so as to bring the water to boiling point. Caustic soda is added to the water until a solution of about 3 per cent. strength is obtained. The whole of the grease is removed from the parts in the process of boiling and comes to the top of the water. Before the contents are removed the grease is drawn off the top. This is done through an overflow pipe which leads into a barrel.

The cradle of parts is then transferred to a second tank of clean, boiling water, which finishes the cleansing and, as the parts are drawn out quite hot, they drain perfectly dry and absolutely clean.

The result, so far as cleanliness of parts is concerned, is considerably better than if kerosene had been used. All minute parts of metal, dirt, and grit go to the bottom of the first cleansing tank.

Oil Put Through Process

The London General Omnibus Co. has a central depot for reclaiming oil and washing rags, and to this depot the barrels of waste oil, as they are obtained from the various garages, and the rags are sent.

At this depot there is a battery of three tanks erected over a furnace, each of which is filled to about two-thirds with water, which is brought up to the boiling point. The barrels of oil as they come in are drawn off into the first boiling tank, a little being added at a time. The oil is thoroughly boiled, and when it overflows into the second tank it has become almost fit for use again, (by the adding of more oil to the first) but it passes into the second tank and is given a second boiling, and then on to the third tank, where it goes through its final stage of cleansing, and from the last tank it is drawn off and run into barrels.

Salvage of Rags

As to rags, their price to-day is much higher than before the war, when they were thrown away after being used. At present every rag is collected in each garage and sent once a week to the central cleaning depot.

VOCATIONAL TRAINING FACILITIES INCREASED

ADDITIONAL machinery is being added by the Military Hospitals Commission to the equipment in the Calgary Institute of Technology and Art for the purpose of affording more returned men the opportunity to take up electrical and mechanical engineering.

The constantly increasing number of men returning from the front makes it imperative for the vocational training centres to be ready to receive them and grant them at once the training necessary to fit them to return to civil life.

In British Columbia, the vocational training facilities at the Shaughnessy Convalescent Hospital in Vancouver are being increased by the addition of twelve extra class rooms, while at Fairmont the equipment is to be supplemented by the addition of a big machine shop and drafting room. Accommodation will also be made for a large shoe repairing department.

Re-educational Centres

Provision for a centre of vocational re-education in Fredericton, N.B., is also being made in the fine vocational building now under construction there.

In carrying out its vocational re-education powers the Military Hospitals Commission has provided as wide a variety of courses as possible at all centres. The policy has been adopted, however, of developing centres of re-education with special equipment at important points as follows, Halifax, Montreal, Toronto, Guelph, Winnipeg, Calgary and Saskatoon.

Centres of re-education for agriculture are being developed at Guelph, Winnipeg, Saskatoon and at Olds, Alta., where the Provincial Department of Agriculture placed one of its agricultural high schools at the disposal of the Commission.

Operators' Instruction Course

EDUCATION PAPER VI.

A boiler carrying 90 lbs. pressure and having feed water at 100 deg. Fahr. evaporated 2987 lbs. of water per hour. What is the horsepower?

A boiler horsepower is equivalent to the evaporation of 34.5 lbs. of water from and at 212° Fahr. per hour. It will be necessary to reduce the above quantity of water to the equivalent evaporation from and at 212°. This quantity is given by the equation We=(H—h)÷ 970.4 in which,

We=the equivalent evaporation.

H=total heat of steam above 32° Fahr., whether wet, dry or superheated.

h=heat of liquid corresponding to the temperature of the feed water.

Substituting in the above equation we have (1187.0—68)÷970.4=1.15.

Since 2987 lbs. of water have been evaporated in one hour, the equivalent evaporation will be 2987×1.15=3435 lbs. and the horse power of the boiler will be 3435÷34.5=100 horsepower nearly.

* * *

What is the equivalent evaporation from and at 212 degrees Fahr. of the evaporation just given? If a boiler evaporates 30 lbs. in one hour from 100° Fahr. to steam at 70 lbs. pressure, how many lbs. water will it evaporate from feed water at 212° Fahr. into steam at atmospheric pressure in the same time?

The equivalent evaporation calculated for the preceding question is 3435 lbs.

When 30 lbs. of water are raised from 100° Fahr. and converted into steam at 70 lbs. pressure heat is required and the amount necessary may be divided into two parts, that necessary to raise the water from 100° up to the temperature of the steam, and that necessary to convert this water into steam.

Steam tables give the total heat content of steam at any required pressure, and quality or superheat. This quantity is figured from 32° Fahr. They also give the total heat of water at any required temperature also figured from 32° Fahr.

And so if we subtract the heat of the liquid from that of the steam we will obtain the total heat imparted to the water. Thus at 70 lbs. pressure dry steam will have a total heat content of 1183.1 B. T. U., and the feed water entering the boiler at 100° Fahr. will have a heat content of 68, and substratcing, we have 1115.1 B.T.U. as the amount of heat imparted to one lb. of the water.

To evaporate water from and at 212° Fahr. requires only the heat necessary to evaporate the water, and none is required for raising its temperature. The latent heat of water at 212° Fahr. is 970.4 and the equivalent number of lbs. of water evaporated under these conditions will be,

1115.1÷970.4×30=34.5 lbs., or one boiler horsepower.

* * *

A boiler has two safety valves, each being 3½ inches in diameter. The size of the wire spring is ⅝ inch square. Required, the allowable pressure on the boiler, the grate surface in square feet and the outside diameter and length of spring.

The area of a safety valve measured at the inside point of contact between the valve and the seat is proportioned to the size of the firegrate according to the following formula

$$A = \frac{37.5 \times G}{B + 15}$$

Where—

A=area of valve in square inches at the point of contact between valve and seat.

G=area of fire grate in square feet.

B=working pressure in pounds per square inch.

It will be necessary in the above formula to assume some definite working pressure and 125 lbs. will be taken. The area of two 3½ inch valves is 22 square inches nearly, and substituting these valves in the above equaton we have

$$22 = \frac{37.5 \times G}{125 + 15} \text{ or } G = 82 \text{ sq. ft. approx.}$$

The diameter of the spring coil may be obtained from the following formula:

$$R = 12{,}500d^3 \div 1.2S$$

where

R=mean radius of coil.

d=side of square=⅝ inch.

S=load on spring in pounds=1375.

Substituting it will be found that R=2" and the diameter will be 4+⅝=4⅝ inches outside.

The springs should have a sufficient number of coils to allow a compression under the working load of one-eighth the diameter of the valve. This will work out to ⅛ of 3½ or about ½ inch. The deflection of a helical coiled spring is found as follows:

$$F = \frac{64 \ P \ R^3 \times .59}{G \ d^4}$$

Where

F=extension or compression of one coil.

P=load in pounds upon spring=1375 pounds.

R=mean radius of coil=2 inches.

G=modulus of torsional elasticity=12,000,000.

d=side of square=⅝ inch.

Substituting we find F will equal .16 inch for one coil. Therefore the number of coils will be .5÷.16=4 free and two end ones, which will be about 5 inches long.

DIMENSION CONVERSION

IN order to conform to the practice of certain shops it is often necessary for the mechanics to convert fractional dimensions to their decimal equivalents, or decimal measurements to the corresponding fractional value, generally in thirty-seconds or sixty-fourths. Various tables have been compiled for this purpose, but it is not always that these are available when desired. To convert a fraction to a decimal equivalent all that is necessary is to divide the numerator (the upper term of the fraction) by the denominator or lower term. Hence to find the value of 7/64 in the form of a decimal, divide 7 by 64 = .109375.

Suppose it is desired to find how many 64ths are contained in the fraction 63/96. This can be calculated in two ways: by converting the fraction to a decimal and then multiplying by 64, thus 63 divided by 96 equals 0.65625 and multiplying by 64 gives 42 or 42/64; or by multiplying the fraction directly by 64 we get the same result. To convert a decimal to an equivalent fraction multiply the decimal by the denominator of the desired fraction. Thus, to change .3215 to the nearest 28th, we get 9.002, which is just 2/1000 over 9/28. To find the number of 64ths contained in the decimal 0.203125, multiply by 64 and the integer of the product will be the desired number of 64ths; thus, 0.203125 x 64 equals 13: therefore the equivalent of the decimal is 13/64.

ONE-AND-SEVEN-TENTHS of the total number of railroad fatalities for the year 1916 were due to the negligence of passengers and 21.4 per cent. to negligence of employees in falling from or getting on or off trains and in walking on track; 5.6 per cent. were due to collisions and derailment of trains. Finally, 5.3 per cent. of the fatalities occurred in shops and were in nowise due to the operation of trains.

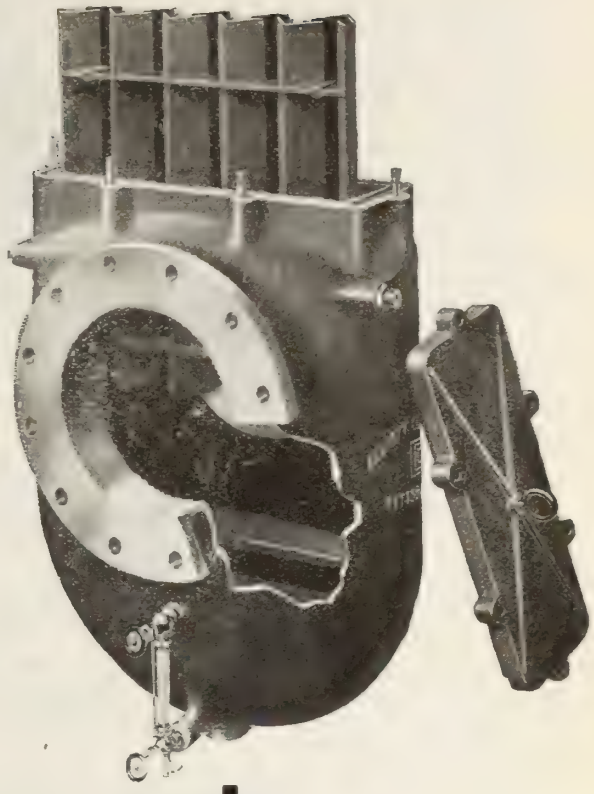
ELLIOTT
Oil Separators

Have baffle plates that can be removed from the Separator and cleaned when they become gummed with oil.

The double row of V-shaped baffle plates in Elliott Oil Separators, Type "P," collect the particles of oil and conduct them out of the path of the steam.



Type "P" Oil Separator showing how the baffles may be removed for cleaning.

In some types of Oil Separators a flat or corrugated baffle plate is interposed in the path of the steam—the idea being that the particles of oil which are traveling at an enormous velocity will hit it head-on and in some manner or other be so broken up that they will cease to exist. The impact or collision may serve to break up the particles of oil into still smaller particles, but little is accomplished toward getting the oil out of the steam as the particles of oil will rebound back where they can be picked up again and carried on with the steam.

A similar action will be observed if you direct a stream of water under pressure against a wall at right angles to the flow of water. The impact breaks up the stream into hundreds of small drops, which rebound back in all directions. If the stream of water were directed against the wall at an angle, practically all of the water would be deflected in the same direction.

This is the principle of the V-shaped baffle plates in the Type "P" Oil Separators. The first row merely directs the stream at the proper angle against the second row of baffles which in turn throws the particles of oil back into the recess angles of the first row so that the oil is completely out of the path of the steam.

The baffle plates are kept moistened with jets of water from a spray pipe (see spray pipe connection at side of accompanying cut.) With the baffle plates in a moist condition the particles of oil readily form into globules or large drops and run down into the reservoir.

The first step in learning more of the Elliott Oil Separators is sending for bulletin "E." It is yours on request.

TRADE GOSSIP

Chatham, Ont.—The city council contemplate undertaking extensive improvement to the waterworks system.

Fredericton, N.B.—The city council are considering calling for tenders for pumps for the waterworks.

Calgary, Alta.—The City Commissioners are in the market for a motor generator set.

North Bay, Ont.—The town council has decided to purchase a steam pump for the waterworks department.

North Vancouver, B.C.—City Council contemplate the erection of a $50,000 filtration plant.

Fredericton, N.B.—The city council are considering calling for tenders for pumps for the waterworks.

Chatham, Ont.—The city council contemplate undertaking extensive improvements to the waterworks system.

Verdun, Que.—Tenders will be called this year for repairs and reinforcements to waterworks and electric plants at a cost of $50,000 for the town council.

Bassano, Alta.—The Canadian Allis-Chalmers, Ltd., have been awarded the contract for a pump and 75 h.p. motor for the town council.

Verdun, Que.—Tenders will be called this year for repairs and reinforcements to waterworks and electric plants at a cost of $50,000 for the town council.

Three Rivers, Que.—The city council is in the market for a centrifugal pump of 3,000 gallons capacity and a 200 h.p. oil engine.

Brantford, Ont.—The Canadian Westinghouse Co., Hamilton, has secured the contract for motor and electrical equipment for the sewage pumping station here.

Lethbridge, Alta.—The Canadian General Electric Co., of Toronto, has been awarded the contract for the new 1,200 kilowatt turbo-generator for the civic power house.

Melfort, Sask.—Town Council contemplates the purchase of a Diesel oil engine.

Port Dover, Ont.—The gas franchise by-law was carried here by 210 for and 10 against.

Alliston, Ont.—The Town Council has decided to purchase a 20 h.p. triplex plunger pump and electric motor at a cost of $2,800. W. J. Cunningham is chairman of the committee which has the matter in hand.

Toronto, Ont.—The Provincial Government contemplates purchasing a cold storage building in Toronto for the purpose of saving the fish caught in the summer and fall for use in winter.

Shelburne, N.S.—Frank J. Carter, of Dartmouth, it is announced, will build and operate a cold storage warehouse at Shelburne, building and equipment to cost not less than $40,000.

Redonda Island, B.C.—The Redonda Canning & Cold Storage Co. are having their fish freezing plant equipped with a 12-ton refrigerating machine furnished by the Armstrong Machinery Co., Spokane, Wash.

Green's Economiser Ltd. has been incorporated at Ottawa with a capital of $50,000 to manufacture all kinds of machinery, plant, mechanical appliances, etc., with head office at Toronto. The incorporators are W. Gilchrist, J. Stewart and H. J. Stuart, all of Toronto.

Picton, Ont.—The Town Council contemplates installing a pump of 1,000 gal. per min. capacity in its waterworks.

Strathroy, Ont.—The Public Utilities Commission is calling for tenders for a pump house. F. R. Smithrin, sec-treasurer.

Montreal, Que.—The Southern Canada Power Co. is contemplating the construction of about 100 miles of high tension transmission line and has called for tenders on poles, cross arms, insulators, cross arm braces, wire and other materials.

Chatham, Ont.—The Dominion Sugar Co. has asked the Hydro Commission for 2,900 h.p. for the operation of a part of their plant using what is known as the Barium process, by which it is now possible to manufacture sugar from refuse formerly regarded as almost impossible.

The Dominion Bridge Co., Lachine, Que., has obtained a large contract for machinery for the British America Nickel Corporation, Toronto. This company is equipping an extensive plant near Sudbury, Ont. The contract includes turbines, turbine blowers, and turbo alternators.

Toronto, Ont.—The Ontario Legislature has voted over $9,000,000 for Hydro-Electric extensions, of which $4,175,000 is for carrying on work on the great Chippawa development at Niagara Falls, from which the province will ultimately secure a minimum of 250,000 additional horse-power.

Kingston, Ont.—The Utilities' Commission has decided to buy four 40 k.w. transformers for the hosiery mill, and a meter for the Campbell power line. A transformer for the street railway will also be purchased from the Canadian General Electric Co., in place of one ordered but not delivered from a firm in the States.

Montreal, Que.—In order to obtain more factory space for their increasing activities, the Mason Regulator and Engineering Co. of Montreal are vacating their present factory for more commodious quarters at 135-153 Dagenais Street. The head office of the company will still be maintained at 380 St. James Street.

London, Ont.—The ice pressure of last month has forced a hole 20 feet wide in the foundations of the waterworks dam at Springbank, which prevents further development of power from this source. Five hundred horse-power was developed there and used for power-load correction and during the present shortage. It will be months before the necessary repairs can be made.

Kingston, Ont.—Manager Folger, of the Utilities' Commission, will report at the next meeting as to the cost of rearranging the smoke stack and some other machinery which was in use when the electric generators were driven by steam, which it is proposed to change over to the gas plant now. It was expected that the work would cost about $1,000 and it was thought better to get a closer estimate of the cost.

Weston, Ont.—Building operations on the new factory of the K. and S. Canadian Tires, Ltd., at Weston, have recently been completed and the installation of the plant equipment is also nearing completion. The heating system is now working and there remains but little machinery to be set up before the plant is finished. Manufacturing operations will commence about the middle of March.

Toronto, Ont.—H. C. Anderson and C. G. Sheldon, representing the Northern Coal Operators' Association, have arrived in the city to impress upon the people of Ontario that the lignite coal mined in Alberta can be brought into this province in case of emergency. They have come here to arrange, if possible, an Eastern movement from the Western mines. Shipments by rail, Mr. Anderson claims, would be the rule, and the freight charges would be about $5 per ton.

Tillsonburg, Ont.—Fire on March 6 almost completely destroyed the main building of the Huntley Manufacturing Co. Its origin is a mystery, and the amount of the loss will probably amount to at least $50,000 on the building, exclusive of machinery, tools and new machines ready for shipment. The main factory of the Huntley Co., which is engaged in the manufacture of elevator machinery, is situated in Silver Creek, N.Y. The Canadian company purchased the plant of the Tillsonburg Electric Car Co. a year ago.

Sudbury, Ont.—The Town Council has petitioned the Provincial Legislature asking for confirmation of certain money by-laws passed by the town. These by-laws are for the issuing of debentures to obtain sums of money to purchase a library site, to get lands for park purposes, for the construction of sewers and water works, for the extension of the present waterworks system and sewers, and for the cost of concrete sidewalks. The money to be raised amounts to about $134,000.

Hydro Commission Gets Extra Power.—The Ontario Hydro-Electric Commission has secured from the Canadian Niagara Power Co. 20,000 horse-power which they have been deprived of for a month or two as a result of the breaking down of two generators at the Canadian Niagara plant. When the machines went out of commission the Hydro asked the Canadian Niagara Co. to supply the power by cutting down on exportations to Buffalo. The company refused, and the Hydro, in spite of appeals to the Power Controller, was unable to get its way.

Oneida Steel Split Pulleys

To Reduce Running Expense and To Save Coal

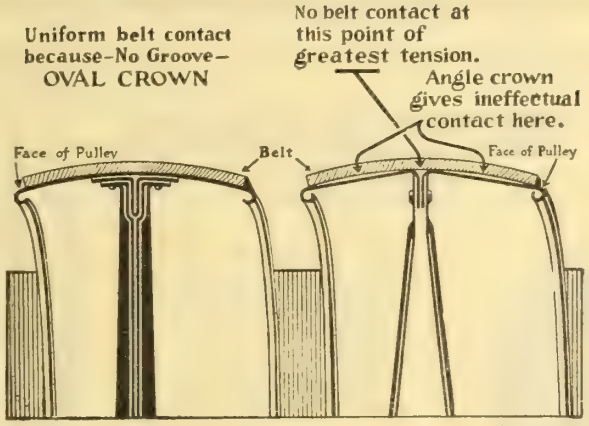
Look to your Transmission

The Oneida Steel Split Pulley is not only right for ordinary line shaft work but it is also successfully built without a change of design, in sizes capable of transmitting 750 H.P.—and more if necessary.

They are furnished as large as 144-inch diameter by 40-inch face.

We carry a large stock of transmission material

For anything mechanical address our nearest house



Uniform belt contact because–No Groove–
OVAL CROWN
No belt contact at this point of greatest tension.
Angle crown gives ineffectual contact here.
Face of Pulley
Belt
Face of Pulley

The economical pulley has a face which insures efficient belt contact.
The Oneida Steel Split Pulley has a one-piece, perfect oval crown, with no groove running through the center. The belt hugs the crown uniformly—thus the greatest amount of belt adhesion is obtained with the least belt tension. Lowering the belt tension means lessening bearing friction.

METLSKIN

BOILER PRESERVATIVE

IT IS NEITHER "COMPOUND" NOR "CURE-ALL"

By arrangement with the manufacturer we are able to make a

60 Day Trial Offer

to any owner or operator of a Steam Plant, whose boilers are Troubled with SCALE. One-sixteenth of an inch of scale means at least 10% more consumption of fuel.

METLSKIN will gradually take out scale and keep it out permanently. It will prevent the common boiler-ills, pitting and corrosion. It will make any boiler a better "Steamer" and save money on coal bills.

METLSKIN is strongly guaranteed **not** to work injury to any part of the boiler system. Nor will it contaminate the steam. For this reason METLSKIN has been standardized in many Paper Mills, Textile Mills, Canning Factories, and other industries where live steam is used in the process of manufacture.

A postal to our nearest branch will bring a GUARANTEE BOND, details of the 60-day Trial Offer, and prices.

III IMPORTANT THINGS

TO CONSIDER ABOUT A SEPARATOR.

I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

Sweet's Separators

GRATON AND KNIGHT

Save Coal

A TON of coal has gone up immensely in cost, but the power you obtain from it remains rigidly the same. It takes about 60 pounds of coal to develop one horse-power for a working day. That is a ton and a half per fifty-horse-power-day. That power should be delivered to your machines with the least possible coal consumption.

A Graton & Knight Standardized Leather Belt will transmit from 25% to 40% more power per inch of width than a belt of any material other than leather. Figure out what that means at the present price of coal. To-day every item must be carefully considered which will, in any way, increase the production of food, equipment, and ammunition. With this greater demand for production and the consequent heavier load on power equipment, the superiority of Graton & Knight Belts becomes more emphatic.

Whether you measure by length of service or maintained efficiency, Graton & Knight Standardized Leather Belts reduce your horse-power cost per year, increase production, and reduce machine interruptions.

Transmission of power is a more important item to-day than ever before and now is the time for you to get at the real facts concerning it.

Clip this Cut! Show it to an Expert Heating Engineer

Even though he does not know the Alberger Heater—which is improbable—the "floating" head feature will win him at once. "This allows for unequal expansion of hot and cold tubes," he will tell you. "Evidently it positively, permanently eliminates expansion strains. A splendid idea! For in most heaters, expansion strains cause endless trouble."

Next he will note the *pure copper tubes.*

"These tubes are corrugated," he will say. "They will transmit 50% more heat than a straight tube of the same size. Make sure they aren't brass, however, for materials segregate in brass tubes and splitting of the tubes, unless they are pure copper, will be frequent."

Alberger Multi-Head Heaters keep up with heaviest hot water demands. They heat water as quickly as it can be drawn—and at a lower cost than any other heater. Both Horizontal and Vertical Types of adequate capacities for every service.

Write for Bulletin 201.

Lloyd George
and the War

COL. JOHN BAYNE MACLEAN contributes to the March issue of MACLEAN'S MAGAZINE a strong article dealing with the need for efficiency in the Lloyd George Government and giving interesting information with reference to the young man who is rapidly coming to the front in Imperial affairs—Sir Eric Geddes, the head of the Admiralty. This contribution is one of a notable series.

"SIXTEEN MONTHS IN GERMANY."

What a Canadian Prisoner saw and heard there—and how he escaped," By John Evans

This article presents a picture of conditions in Germany and gives many new facts with reference to what is going on in that country. The writer worked for sixteen months in the mines of Westphalia and came in close contact at all times with the miners. The story of his escape is a thrilling one.

"CANADIANS IN MESOPOTAMIA."

By a Canadian Medical Officer.

Little has been known heretofore of the campaign in Mesopotamia. This article gives details of the campaign and of the part which Canadians are taking in it. It shows how the inefficiency of the first campaign has been done away with and how splendidly organized the British army now is. The article contains many interesting anecdotes of adventure on that front.

"LABOR THE DOMINANT FACTOR."

By Agnes C. Laut.

This is an article on the war situation as it is developing on this side of the Atlantic, showing that labor is becoming a dominant factor. In the United States the antagonistic attitude of the labor union is dying out and being replaced by a strong desire to assist in war measures.

"CANADA'S NEW BOSS."

By H. F. Gadsby.

A political article, dealing with the "man behind" Union Government. It gives interesting and exclusive information with reference to the political situation at Ottawa as it is developing since the election.

"A CASUALTY."

By Robert W. Service.

A war poem which tells of an experience which actually happened to Service while driving a motor ambulance on the Western Front. It will be illustrated by C. W. Jefferys.

Fiction in the March Number

"BY THE TIP OF AN EYELASH," by A. C. Allenson, illustrated by R. M. Brinkerhoff. A bright story combining business, love and horse racing.

"THE GARDEN OF SPICES," by L. M. Montgomery, illustrated by F. Weston Taylor. This is a most unusual and charming love story.

Two long instalments of the two serials **"THE PAWNS COUNT,"** by E. Phillips Oppenheim, and **"THE MAGIC MAKERS,"** by Alan Sullivan.

"THE GIRL ON THE VERANDAH," by Arthur Beverly Baxter, who wrote **"The Man Who Scoffed,"** and **"Mam'selle Butterfly."**

Regular Departments and Features

There are the regular features and departments: Review of Reviews; Business Outlook; The Investment Situation; The Nation's Business; Books; Women and Their Work. A food article by Miss Chapman is a feature, and a new Spring Department on Seeds and Garden Culture starts in this number.

MacLean's Magazine
At all News Stands—20c.

Toronto, Ont.—Permit was granted last Thursday to the Dominion Shipbuilding Co. to construct a one or two-storey main building at the foot of Bathurst street on the Harbor Commission property at a cost of $175,000. The building will be of steel throughout and faced with hollow tile. The site leased by the company covers about 16 acres, and five shipbuilding berths will be laid down.

London, Ont.—The Public Utilities' Commission has directed to the Dominion Natural Gas Co. a request for full particulars concerning the strike of gas in a well near Port Talbot, thirty miles from London. The company is reported to have found gas there 70 miles from any other known field. The strike was made at a depth of 1,506 feet, and the yield is now estimated at from 5,000,000 to 7,000,000 feet a day. London will ask for a supply in order to be able to meet the coal shortage next winter.

Fuel From Garbage.—The City Council of Guelph has closed a contract with L. R. Long, of the Ontario Oakoal Co., for the construction of a plant in that city. The garbage of the place, with the exception of such non-combustible matter as crockery, glassware, etc., is to provide the raw material, and the plant is to turn out a fuel in briquette form to retail at $7 a ton. The city provides a free site, water and exemption from taxes, excepting for local improvement and patriotic purposes. Mr. Long guarantees to have a capacity of 50 tons per day of his new product.

Montreal, Que.—J. M. Hutcheson, general manager of Montreal Tramways Co., states that the second auxiliary steam plant at Hochelaga, consisting of a steam turbine with a capacity of 12,500 k.w.h., or about 17,000 h.p., will be installed towards the end of April or at the beginning of May. Asked as to how the first auxiliary plant was working out, Mr. Hutcheson replied that it was doing very well, being used in rush hours, such as in the morning and evening, when requirements for electric current are far above normal, besides which it can be used in case of any failure of transmission of hydraulic power.

Plan Big Outlay on Hydro System.—Estimated expenditures of over $9,000,000 for Hydro-Electric extensions, of which $4,175,000 is to pay for work on the Chippawa Creek development, are included in the Ontario Provincial estimates totalling $9,741,662. For Niagara system extension the sum of $2,865,000 is being voted, for the Central Ontario system extensions $588,000, for the Severn system $405,000, Eugenia Falls system $233,000, Port Arthur system $150,000, St. Lawrence system $251,000, Rideau system $117,000, Nipissing system $60,000, and for service buildings and miscellaneous, the sum of $100,000 is asked.

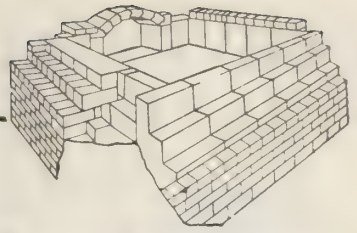
Boiler Inspection Act Amendment is Proposed.—Consideration was promised by Hon. F. G. Macdiarmid, Ontario Minister of Public Works, to a deputation headed by J. Leonard, of London, Ont., recently, asking that the Boiler Inspection Act be amended. The act now provides for the inspection of all boilers from the time the plans and specifications are submitted, but unless the boiler requires repairing it is never inspected in the interim, except by insurance companies. The inspection is made by stationary engineers. This is objected to by the manufacturers, as they claim that the stationary engineers are not competent to judge, because of his employment by a company owning the boiler.

Quebec, Que.—With the exception of the closing of some temporary sluices, the great dam at the head of the St. Maurice River is now finished, giving this province the largest artificial water storage in the world. The reservoir has an area of not less than 300 square miles. It is the completion of a work which has involved more than five years of investigation and construction, and an expenditure not far short of $3,000,000. On July 25, 1915, the contract was finally awarded to the St. Maurice Construction Co., who made an arrangement under which the supervision and organization of the contract work was placed in the hands of Messrs. Fraser, Brace & Co. of Montreal.

Engineers Will Discuss Fuel Problem.—Because of the great public interest in fuel and power, the Canadian Society of Civil Engineers has called a public session for March 26 and 27 at the University of Toronto, Physics Building, to discuss coal, wood, peat, gas and electricity, as related to coal and kindred problems. Arthur Hewitt will speak on "Gas," B. F. Haanel on "Peat and Natural Resources," Prof. Zavitz on "Wood," and Sir Geo. Bury on "Transportation," John Murphy on "Railway Electrification," P. H. Mitchell on "Electric Heat." Premier Hearst has been asked to preside, and invitations have been sent to the Provincial Government, the City Council, the Board of Trade, and the Canadian Manufacturers' Association

Ammonia Shortage Feared for Artificial Ice Making.—The United States Food Administration issues the following statement: The attention of the Food Administration has been called to articles appearing in various New York papers by which it is indicated that plenty of ammonia will be available to make ice next summer; that there will be no commandeering of ammonia in New York; and that there will be a sufficient supply of the commodity to permit the manufacture of the customary amount of artificial ice. The Government can not give assurance that there will be a sufficient supply of ammonia, nor that the manufacture of the customary amount of artificial ice will be possible. There is danger of a serious shortage of ammonia, and steps are being taken to have as large as possible a harvest of natural ice to meet any possible shortage of artificial ice.

Sarnia, Ont.—A number of factories here have been affected by the order issued by the Ontario Railway Board, cutting off the supply of natural gas for manufacturing purposes. The firms in



Gates Boiler Furnace

Patented 1916

Will last three times as long as ordinary good grade Fire Brick. These blocks are inter-locking, and made so that any handy man or fireman can renew them without disturbing any of the other brick work.

Attention, Water Power Users

FOR SALE

Four standard 55-inch Crocker Turbine Water Wheels, fitted with graduating gates, complete with shafting, gears, etc. Wheels were manufactured by Jenckes Machine Company, and guaranteed to develop 150 H.P. when horizontal shaft is running at 150 R.P.M. when working under an effective head of four feet. Have never been used and are as good as new.

H. Corby Distillery Co., Limited
CORBYVILLE, ONTARIO (p3b)

Are you allowing money to slip through your fingers?

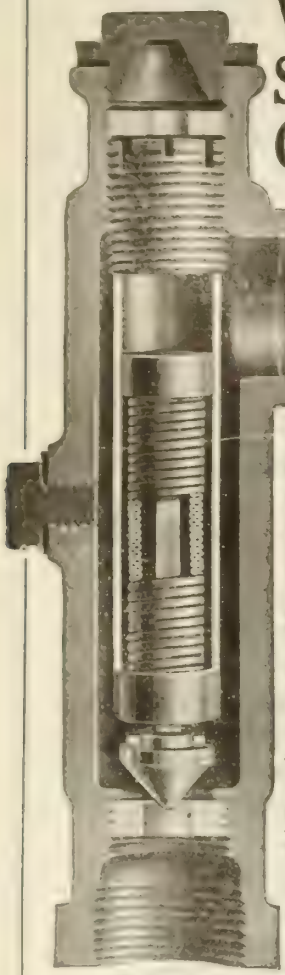
Examine your coal bills and think this over.

Why not let us show you how to return condensation back to your boiler, at such a high temperature that you can't help but show a saving?

At least send for literature.

Geo. W. Cole, Limited
2002-4 Dundas St. W., Toronto, Ont.

INDIVIDUAL TRAPPING WILL SAVE COAL



Because you stop the flow of Steam at every point where a trap is installed and pass only condensation to your receiving well.

Any method of carrying live steam with the condensation to some distant point to a large, cumbersome type of trap, which also requires steam pressure to make it discharge, is not only old-fashioned but wastes a large quantity of steam by useless radiation, requiring heavier coaling at boiler to keep steam pressure at required point.

Steam Trap SARCO

can be installed at five different places for the price of one float or bucket type of trap, and allow nothing but condensation to pass, saving you that much coal in operation.

The Sarco principle of construction is basically sound, it uses hydraulic pressure: the expansion of a liquid by heat and the contraction of the same liquid when cooled. There is only one moving part, and none to get out of order.

They are small in size and large in capacity.

COAL IS SCARCE

and individual trapping is a way to save

We will demonstrate on a 30 days' free trial basis.

If you want to save at five points in your plant instead of one

Sarnia affected by the order are not using the gas for fuel, but for power-generating. The gas engines are in such plants as the Lougheed Machine Co., Sarnia Fence Co., Cleveland-Sarnia Saw-mills Co., Doherty Stove Co., Canadian Printing Co. and others. These firms will have to close unless they can either obtain special permits to use gas or the order is rescinded. The firms cannot secure hydro equipment owing to the conditions prevailing. No gas has been supplied any local firms for fuel since last November. The big plant of the Imperial Oil Co. is not affected. Its gas supply for fuel was cut off with others last November, and since that time oil and coal have been used.

Ottawa, Ont.—Tenders will be received until March 18, 1918, for heating and ventilating equipment required in the reconstruction of the Parliament Buildings. All tenders to be based on the execution, erection, and completion, together with the furnishing of all materials, tools, appliances, scaffolding, apparatus and labor required for the installation of the heating and ventilating equipment as called for in the plans and specifications. All information can be obtained at the office of the general contractors, P. Lyall & Sons Construction Co., Ottawa. A set of plans and specifications may be had by depositing an accepted bank cheque for twenty-five ($25.00) dollars, made payable to the Honorable the Minister of Public Works, which will be returned if the intending bidder submits a regular bid.

Quebec Railway to Stimulate Manufacturing.—At a meeting of the Quebec Railway, Light, Heat & Power Co., plans were discussed in connection with a propaganda to advertise the company's capacities, with a view to inducing Western capital into the Province of Quebec, particularly on the company's lands in and around the City of Quebec, the purpose in view being the furnishing of electric power to the industries backed by the capital induced. The company has water powers at Montmorency Falls, the Natural Steps just above the falls, at the Chaudiere Falls, and on the Jacques Cartier and Ste. Anne rivers. The total amount developed is 48,000 h.p., and there is further power, as yet unharnessed, of 25,000 h.p., with an additional 3,000 when the proposed dam on the Jacques Cartier river is completed. The company is placing before the Government at Ottawa a proposal asking that the company electrify the new Quebec Bridge, and take all trains across by means of electric engines.

WILL RELIEVE GAS SITUATION

THE Ontario Legislature has unanimously passed the Natural Gas Act, giving the Ontario Railway and Municipal Board wide powers to control and regulate the production and transmission, distribution and sale, disposition and consumption of all the natural gas produced in Ontario.

This was an emergency measure taken to relieve within the next twenty-four hours the serious situation existing in various parts of the province which depend on natural gas for heating purposes, but especially the city of Windsor and district.

The Ontario Railway and Municipal Board is now in complete control of the situation, and has power to brush aside all private corporations, and the Minister of Lands, Forests and Mines, who introduced the measure, made it clear that the people of the province are to have first call on the gas supply for the purpose of heating their homes,and that important industries engaged in the manufacture of war supplies and the production of food supplies are to come second.

"Belmont" 1903 Special Hydraulic Packing. For Hot or Cold Water Boiler Feed Pumps (Inside or Outside Packed) and for Hydraulic Work It Has No Equal.

Pressures up to 10,000 lbs.

Cannot Split, Swell or Pinch

We guarantee Belmont Special Hydraulic Packing to give absolute satisfaction under the heaviest pressures, and when exposed to acid or alkaline waters. We know that it is made right, and from the best material, and that "Belmont" is absolutely the "last word" in packing arguments.

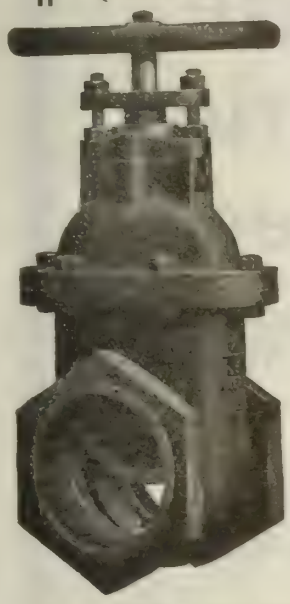
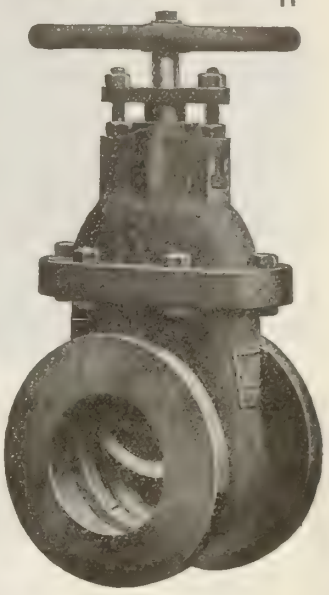
KERR
("New KEYSTONE" Pattern) GATE VALVES



If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.



When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

Kerr Engine Co., Ltd., Valve Specialists **Walkerville, Ont.**

The function of lubricating oil is to give the greatest ease of motion to all parts of the engine, so that every possible atom of power may be transmitted to the machines. An oil that will do this will have effect on other divisions. Ease of operation would mean elimination of friction, no wear on the bearings, less oiling. Pure oil would be a decided labor-saving, cost-reducing, efficiency-promoting factor in the engine room. A great many Canadian manufacturers have pronounced our "Non-Corrosive Cylinder Oil" pure. We, who know its construction, pronounce it pure. Get in touch with us.

WRITE FOR PRICES.

Use Graphite for Cylinder Lubrication and Cut the Cost.

Dixon's Flake Graphite forms a wonderfully smooth, anti-friction veneer over the interior of the cylinder.

It furnishes better lubrication than can possibly be obtained by oil alone.

DIXON'S Ticonderoga Flake Graphite

will restore cut and scored cylinders and valves to perfect smoothness. Sticking and groaning valves disappear entirely. Rod packings last indefinitely.

Write for booklet No. C, showing some of the types of engines on which Dixon's Flake Graphite is being used, and explaining method of successfully introducing it into the cylinder.

Positive Lubrication Assured

WHEN YOUR PLANT IS UNDER THE CARE OF THE

BOWSER ESTABLISHED 1885 **Lubricating Oil Circulating Filtering** **SYSTEMS** THE STANDARD ALWAYS

It is an everyday occurrence for some factories to have shut-downs once or twice a day, and the cause of this, many times, is improper lubrication. Dirt and grit gets into the oil during use. When such oil comes in contact with the bearings there is at once an unnecessary friction and "hot boxes" result—then shut-downs follow.

With the Bowser Filtration Systems shut-downs are avoided. More power is obtained from the engine and less wear and tear on the parts is assured. The dirty oil is taken by the system into its filtering compartment, where all the impurities are extracted. From this compartment the oil is returned to the clean oil tank ready for use again—as good as new. This system not only saves machinery, but it saves oil, as well. The refuse and dirty oil can be drawn from the chamber used to collect it and many uses can be found for it. This saving alone amounts to a sum worth considering.

Bowser Systems are built for any sized plant, to fulfill any requirement. The 6F shown below is especially adapted to plants whose engines are on ground floor instead of in basement, and where large volumes of water return with the dirty oil. Let us be your advisors in lubricant and power problems. Write to-day, explaining your requirements—no obligations on your part.

Success and Your Associates

ALWAYS associate with men who are earning more money than you are. Such is the advice given by a man whose name is known the world over for his own success and the business which he created. It is good advice of a certainty, but we are not urging that it is the best advice. At the same time it is wise to associate with better or bigger men than you are yourself. because you are likely to be lifted up to their levels.

Most of us would probably like to be the intimates of J. P. Morgan, or of John D, or of Charlie Schwab, or Canny Andrew. If we had a speaking acquaintance with John Wanamaker, or Lord Beaverbrook, or Lord Shaughnessy, and with other distinguished and successful men, we would take comfort from the fact.

And most of us would feel rather small and uncomfortable if we were placed beside President Woodrow Wilson at a dinner table, or beside Sir Robt. Borden, Sir Herbert Holt or Thomas Findley. And the reason would probably be that we know so little of the knowledge that really counts. If these great men engaged us in conversation we would probably find ourselves knowing very little about the things that matter.

This will illustrate the point:

Here's a true story. A Toronto manufacturer found himself on a train going to Albany in company with a number of distinguished Americans about to attend the inaugural ceremonies of a State Governor. A washout led to a delay, and the Canadian was thrown into close association with senators and congressmen and prominent lawyers. They bantered the little Canadian about Canada. He had the pluck of a bigger man. He had been a constant reader of THE FINANCIAL POST, and had absorbed many facts about Canada. He surprised his American traveling companions with his positive, well-informed and wide knowledge of Canada. When the company reached Albany, the Canadian was persuaded to attend the ceremonies, and was introduced as the man who knew all about Canada. The Governor was interested in Canada, and said so, and the little Canadian found himself telling the story of Canada very ardently to a very attentive listener, much to the amusement of his friends who introduced him.

This man made a hit on that journey, and many friends. One of the company gave him a stock market tip worth a fortune.

The point of this story is: You, as a Canadian, can make yourself informed very fully and intelligently if you become a regular reader of THE FINANCIAL POST. You can make yourself a worthy companion and intimate of presidents and magnates. The world likes to listen to men who know something well, and who can talk interestingly and informingly on the subject of their study.

You can become worth listening to if you know your Canada well. And you can get the kind and amount of knowledge concerning Canada which will make you interesting to others if you will read THE FINANCIAL POST regularly each week.

IF you read THE FINANCIAL POST REGULARLY you will find yourself keeping company with the highest paid staff of editors engaged on any publication in Canada—trained men who know how to make others know what they know and learn.

You will find yourself living in a most interesting world—the great, throbbing world of business. You will have your thoughts tremendously stimulated and helpfully directed. You will find yourself becoming a fit table companion for big men — this because you will have knowledge of a quality that will keep you from shame.

What is it that keeps you and THE POST separated? It cannot be its subscription price of $3. Probably it is because you are not very well acquainted with this paper.

We are going to put it to you this way: If you have the desire to be worthy of association with big men, then prepare yourself for such association by reading THE POST, and to make acquaintance easy, we provide the coupon below. It offers you THE POST for four months for a dollar bill.

MUELLER

Globe and Angle Valves

BUILT from actual, practical experience. Made of the famous *MUELLER* steam metal and fully guaranteed against all defects in design and construction. Not a Valve, but *the* Valve.

¶ *MUELLER* globe and angle Valves can be repacked under pressure. The disc is so designed as to adjust itself to any position and still receive the thrust of the spindle on the center line; thus preventing any distortion to the seat or diaphragm. The pipe threads are full length, and are tapered to conform to I. P. Threads, insuring perfect joints.

¶ Full sized and unobstructed passages guarantee full service. The large Hexagons allow an excellent wrench grip and our design puts the strain where it belongs, so that there is no danger of distorting either the body or the bonnet. Furnished with enameled, Malleable iron wheel handles. Every *MUELLER* Valve tested to beyond unusual service conditions. Write for prices.

MUELLER gate and check valves, steam cocks, etc. rank highest in every branch of exacting service.

All Down the Line—

You'll find sizes and types of

Jefferson Unions

for every union need—why not standardize them and put an end to pipe line troubles throughout your plant?

The Jefferson feature of forcing the brass seat ring into a recess just back from the runway and contents of the pipe makes it corrosion-proof and at the same time much more durable than a bronze or brass seated union handled in any other way. Then the weight of a Jefferson is greater than any other union of similar class—another logical "reason why" they are most successful.

If your jobber can't supply Jeffersons, a line direct to us will bring you the name of our nearest dealer and the Jefferson Book "Unions"—a treatise on pipe line connections which you'll enjoy reading.

Jefferson Union Features

Ground ball brass-to-iron or iron-to-iron joint, ground with mate and never separated.

Sloping shoulder and large play in the ball end, which is of assistance in connecting piping out of line.

Standard pipe threads tapered to fit the pipe. Coarse nut threads for quick adjustment.

Heaviest of its class made and sold at reasonable prices.

JOHNS-MANVILLE
Power Plant Service

JOHNS-MANVILLE SERVICE
COVERS THE CONTINENT

IT HAPPENS every day to hundreds of you engineers—you mention your problems to a Johns-Manville salesman who drops in and that's his cue to get together with you and help. The next minute finds you working together over a piping design, to kill off wet steam that's laming the pump or whatever the bother happens to be.

We are not competing with the consulting engineer. But call it service, salesmanship, or common sense—the fact remains that no Johns-Manville man is contented with mere order taking. For back of every product he sells is a Johns-Manville branch, home office, factory and technical staff, whose primary aim is to make "*Johns-Manville*" a tradename in the power field for all around service.

Canadian Association of Stationary Engineers

Incorporated May, 1887 — Incorporated at Ottawa, June, 1917

An organization having as its aims and objects:—

To promote the knowledge of its members in the art and science of Steam Engineering.

The dissemination of information beneficial to the members of the association in the discharge of their calling.

To further and protect the interests of competent engineers, and receive such as members of this organization.

To secure, through proper legislation, the greatest security in operation of steam plants.

To assist unemployed members to secure positions.

To maintain freedom of action between employer and employee.

The members of the Association subscribe to the above in the full belief that ability and knowledge of one's profession are necessary to insure the highest degree of success.

Labor Study Energy

These three essentials have been responsible for the success of the world's greatest men. They are no less essential for yours. We cannot all become great, but this fact does not lessen the necessity for the exercise of these essentials in our individual occupations. Cool, calm, calculating judgment characterizes the successful power house operator of to-day. The demands on the engineer of to-day are many, and the obstacles in his path are great. To assist in the overcoming of these and help the accomplishment of great works, material, moral and educational, is the desire of all our members.

The benefits accruing from association with members of his fraternity, the opportunity to benefit by their experience, and the inspiration to greater effort by reason of their success render membership in this association indispensable to all progressive engineers.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

Is the Sign To Go By

D. K. McLAREN'S LEATHER BELTING

Keep the OAK LEAF in mind the next time you are buying belting—it will serve you as a guide to the better belting service in your plant.

The use of this belting reduces slip to a minimum, thereby saving a considerable amount of power. It also saves a remarkable amount of time, labor and attention, because there is hardly any stretch to it.

Genuine British-Oak Tanned

Therein lies the secret of the toughness and durability of D. K. McLaren's famous Leather Belting. The British Oak Tanning Process is the best method known for treating leather for belts, and this, coupled with the expert choice of flawless back leather makes these D. K. McLaren products as serviceable as a leather belt can possibly be.

We would like you to know what others think of it—write for list of users, then ask them.

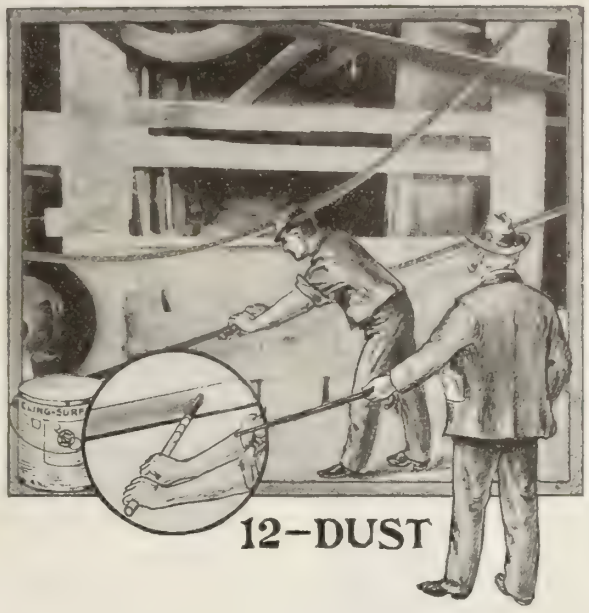
ALEXANDRIA, ONTARIO



Dont Claim Exemption

—because the air is filled with dust,
—because this dust settles on the belts,
—because it makes a belt dressing "ball up"
are no reasons at all why your belts can't have the benefit of

CLING-SURFACE Belt Preservative

Just wipe the dust off first.

Then with the swab (as shown) treat the face of the belts a little at a time.

Your belts will absorb CLING-SURFACE very quickly, leaving a clean, not sticky, surface.

It will be smooth, velvety, and will not slip.

Nor will it hold the dust.

Your drives will last longer, do more work, cause no trouble, and can be run easy or slack under full loads.

They will never again have static electricity.

* * *

Results like these PAY.

Are you willing to try this treatment if such trial **costs you nothing?**

Then write to-day for the 25-pound can we have waiting for you.

Use it sixty days.

If you're satisfied, pay us for it. If not, we will take back what you have left, charge you nothing for what you've used, and pay the freight both ways.

ALL CHEERFULLY—no hard feelings!

Remember, use CLING-SURFACE and you won't need belt dressings.

Stationary and Hoisting Engineers

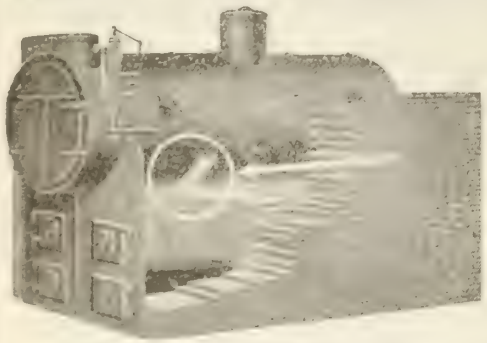
Everyone operating a STATIONARY steam plant of 50 h.p. or over in the Province of Ontario must hold a Stationary Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse power, and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Application forms for obtaining STATIONARY or HOISTING Engineers' Certificates, may be had upon applying to the Chairman.

HON. F. G. MACDIARMID, Minister of Public Works and Highways.
W. C. McGHIE, Chairman of Board.
W. A. RIDDELL, M. A. PH. D., Superintendent, Trades & Labour Branch.

PREVENT FIRE CRACKS and LEAKS



by installing the National Boiler Seam Protector. Attached by anyone in 30 minutes. Endorsed by Engineers, Boiler Inspectors and Insurance Companies. 3,500 installations made in last two years. Write for list of Canadian and U. S. A. users.

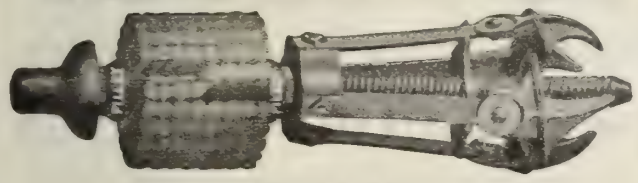
THE BEST IN PUMPING MACHINERY

The Smart-Turner Machine Co., Limited

HAMILTON, CANADA

The Simplest and Best Cleaner on the market is



PILLEY'S

Combination Flue Brush and Scraper

Guaranteed not to break or the wires to pull out or lay over. A simple turn of the hand adjusts it to the tube, and the brush removes what the scraper loosens.

For sale by leading Canadian jobbers

Manufactured by

PILLEY PACKING & FLUE BRUSH MFG. CO.

623 South Third Street ST. LOUIS, MO.

Eastern Office: 71 Fulton St., New York.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914 With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

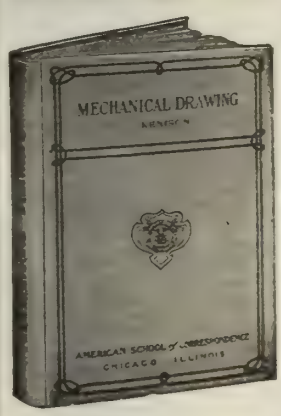
Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID, Minister of Public Works and Highways

W. A. RIDDELL, M.A. Ph.D., Supt. Trades & Labour Branch

D. M. MEDCALF,
Chief Inspector of Steam Boilers.



Mechanical Drawing

By Ervin Kenison, S.B.

Instructor in Mechanical Drawing, Massachusetts Institute of Technology

176 pp., 140 illus. Cloth binding. Gives a course of practical instruction in the art of Mechanical Drawing, based on methods that have stood the test of years of experience. Includes orthographic, isometric and oblique projections, shade lines, intersections and developments, lettering, etc., with abundant exercises and plates.

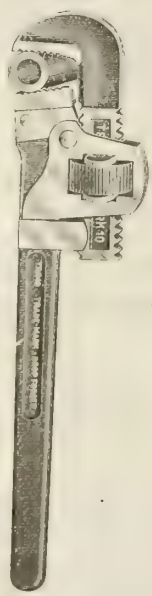
The Wrench of 25% Greater Efficiency

TRIMO PIPE WRENCH



Two new features have been recently added to the Trimo Pipe Wrench, namely Nut-Guards, in all sizes, and unbreakable steel frames, in leading sizes.

The Nut-Guards prevent the accidental rotation of the nut while in use.

These improvements add 25% to the usefulness of the tool.

The Trimo Pipe Wrench is made with wood handles in 4 sizes, 6-in., 8-in., 10-in., 14-in. and in steel handles in all sizes, 6-in. to 48-in. inclusive.

All Trimo Pipe Wrench parts are interchangeable.

The inserted jaw in the handle can be readily replaced when worn, thus adding to the life of the tool.

Nut with Nut-Guards

The Anderson Model "D" Steam Trap

Steady and Continuous Drainer

Disposes of Condensation as Fast as it Accumulates in Steam Coils, Jackets, Radiators, etc., Without Reducing Pressure or permitting Live Steam to Escape.

All Parts Interchangeable

All parts are machined to solid gauges, thus insuring absolute accuracy.

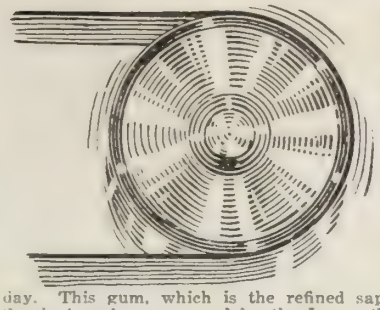
The trap is so constructed that you can change the valve and seat from high to low pressure or vice versa in five minutes without disturbing or unscrewing a single steam joint or pipe connection.

A removable strainer is part of the equipment. It prevents pieces of scale, packing, etc., from entering the trap.

Every "Anderson" Model "D" Steam Trap is fully guaranteed to give satisfactory service.

Drop us a line to-day for valuable description booklet.

The V. D. Anderson Co.
1935 West 96th St., Cleveland, Ohio



Balata gum does not deteriorate with age.

From what we know of this gum it would be safe to assume that belting impregnated with it would be in just as good shape and ready for use in 100 years from now as it is to-day. This gum, which is the refined sap of the Bocia tree in South America, was used by the Incas, the original inhabitants of Peru, to coat their shields, which were made of bull hide. The gum was used both as a preservative for the leather and also because this coating was exceedingly tough. These shields were found hundreds of years after and were in a perfect state of preservation. The gum coating was just as pliable and tough as if recently made. This is the gum that is used in

LANCO BALATA BELTING

and is not used merely as a cement to hold the plies together, but the whole fabric passes through a solution of this gum. The solvent on evaporating leaves a solid mass of balata, not only between the plies, but in the duck itself. This gum is responsible for the properties which make the belt really waterproof and long-lived. It is an expensive belt, but will give the service. Order your supply in rolls, as it will not deteriorate in your warehouse. Special prices for full roll lots.

Federal Engineering Co., Limited
172 John Street, Toronto, Ontario

Morehead

Back to Boiler

SYSTEM

Drains Your Steam Lines Back to Boiler Automatically Without Pumps

After steam's expansive energy is exhausted, there are heat units left. These the Morehead System returns to your boiler as pure HOT feed water. It lowers your fuel cost by 10 per cent.

It would pay you to talk with the owner of a plant in which the Morehead System is installed. **Write.**

DAVIS
PRESSURE REGULATORS
CAN SAVE STEAM IN EVERY PLANT—IN YOUR PLANT

In big power plants and in little plants, correct steam pressure for the various uses is essential to economical operation. The Davis Pressure Regulator saves steam by reducing the generated high pressure to the lower pressures as needed.

The desired pressure is obtained by adjusting the number of weights on the lever arm. The pressure is *weighed*, because the Davis Pressure Regulator is built like a pair of balance scales—just as simple and just as accurate. As simple and unfailing as the law of gravity, because it is controlled by gravity. There are no springs; no diaphgram to give trouble.

The new valve booklet contains some mighty useful information about valves and piping and will be sent free on request to the G. M. Davis Regulator Co., 434 Milwaukee Avenue, Chicago

UEHLING WASTE METER
COMBINED
CO_2 AND TEMPERATURE RECORDER

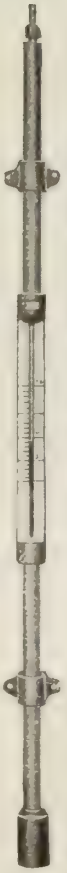
Record of CO_2 and stack temperature on one chart.

Does your fireman know how much fuel he is wasting? Do you know?

The **Uehling CO_2 Recorder** makes a complete 24 hr. record of your combustion efficiency and the **CO_2 indicator at the Boiler Front** holds the fireman responsible.

Get more **Steam** per pound of **Coal** and reduce your annual fuel consumption.

Let us know the number and size of your boilers and coal consumed per year, upon receipt of which information we will be glad to send you full particulars.



CO_2 Indicator for Boiler Front

Let us hear from you. We are pioneers in the manufacture of Indicators and Recorders for Power Plant purposes.

Send for our Bulletin No. 110.

The Real Efficient Lamp for Power Plants

WHEN England first made munitions in present-day quantities, holidays were forbidden—"to increase production." Presently holidays were *enforced*—for the same reason! Why the reversal? Because it was found that no man can work to utmost capacity *under constant strain.*

If your plant is inefficiently lighted *your* workers are under a *strain* that affects their capacity to a very appreciable extent — they are laboring under a handicap that in your own interest you should remove.

TWENTY-FOUR hours of sunlight—or its *closest* equivalent are possible to the plant equipped with Laco Nitro Lamps.

They represent the latest development of the tungsten bulb — a tungsten filament burning in nitrogen gas. They consume less current — possess a longer utility—yet give a greater candle-power per watt than any other type of lamp. Decide to-day with your nearest dealer that Laco Nitro Lamps shall cut your cost and increase your plant's efficiency!

LACO NITRO LAMPS

Sold by the leading Electrical and Hardware Dealers, or the

Don't buy that New Electrical Apparatus Just Yet

WE can supply you with high-grade apparatus that has been slightly used and discarded through no fault of its own, at an **immense saving in cost.** For instance, in many cases we take over entire plants simply because of changed conditions such as increased capacity, change of system, etc.

EVERYTHING IS OVERHAULED AND REFINISHED BY US AND **GUARANTEED** AS GOOD AS NEW, BOTH ELECTRICALLY AND MECHANICALLY.

Our catalogs of offerings should be in the hands of every power plant superintendent each time they are gotten out, and it will be worth while for anyone interested in this class of power plant equipment to be on our mailing list to receive all offerings.

Nearly all of the principal power, lighting and street railway plants in the United States are our customers.

WRITE FOR OUR LATEST CATALOG of Power House Equipment, Street Cars, Motors, Hoists, Compressors, etc.

MACGOVERN & COMPANY, Inc.

114 Liberty St., New York City

Have you a Particularly Troublesome Steam Line?

Then give these Homestead quarter-turn Valves an opportunity to show you how quickly they can relieve you of a troublesome situation!

They have relieved others and will serve you likewise.

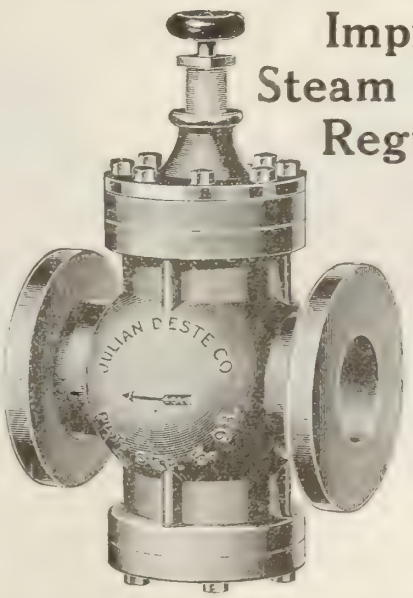
Homestead Quarter Turn Valves

are giving the best of service where other valves have failed entirely.
They greatly outlast ordinary valves, and if there is any difference in the price of a Homestead compared with ordinary valves, the Homestead will make up the difference in longer service.
Glad to demonstrate the superiority of the **Homestead Quarter Turn** by sending one for trial. Write now.

Homestead Valve Mfg. Co.
HOMESTEAD, PA.

CURTIS Engineering Specialties

Improved Steam Pressure Regulator



For Universal Application to all the varied and various conditions under which a reduced pressure of steam, water or other fluid is required, this Regulator (see illustration) has no equal. It is compact and self-contained, without levers, weights or projections.
No glands or packing; no drip or leak of steam or water. Suitable for any boiler pressure; made entirely of metal: is a lock valve, very simple and sensitive.

The universality of use of this Regulator is one of its best features, but it is in **Steam Heating** that its use is most common and obvious. Send for leaflet fully descriptive of this Regulator (contains price list) to the manufacturers.

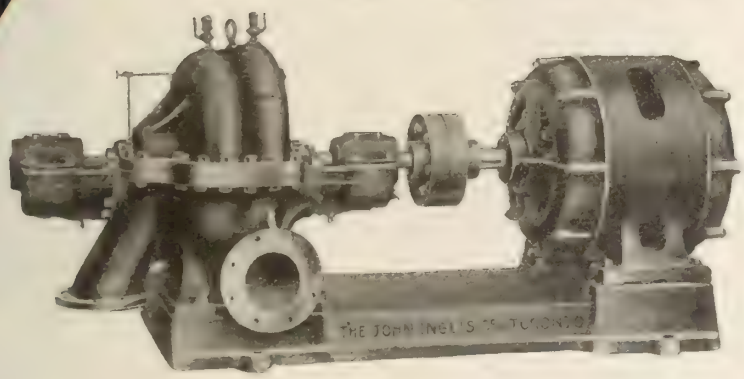
INGLIS

TURBINE PUMPS



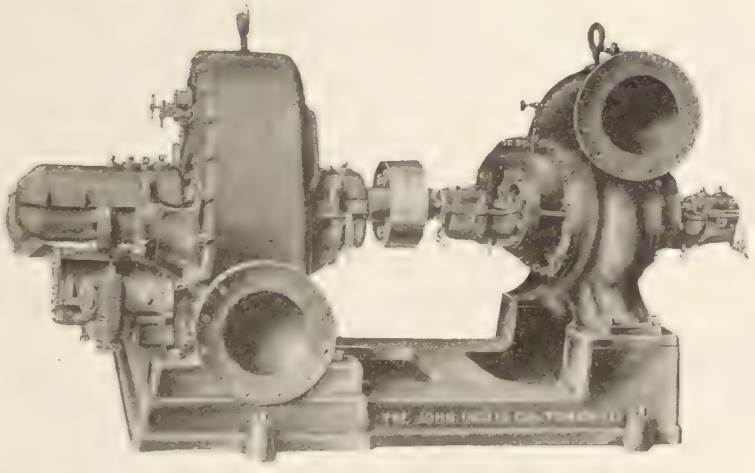
Inglis Turbine Pumps are used in power plants throughout Canada with unqualified success. They set the standard for the utmost efficiency in Turbine Pumps. They are durable, reliable, economical.

Illustration No. 1 shows our Multistage split case Turbine Pump for medium and high pressures. Direct connected to electric motor.

Illustration No. 2 shows double Suction Pump for circulating low or medium heads. Direct connected to steam turbine.

Oil ring bearings, hydraulic balance and water-cooled thrust bearings are features of their ideal construction.

Impellers and passages are highly finished, all working elements being carefully balanced against vibration.



Let Inglis Engineers give you their advice. Their knowledge and wide experience places them in a position to advise thoroughly and efficiently on all problems affecting Turbine Pumps.

The Inglis line includes Boilers, Engines and Pumps. Full information on request.

SIGHT-FEED LUBRICATORS

Are Reliable and Dependable

The Peerless —

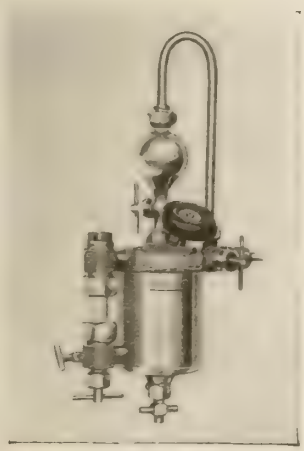
IS STRICTLY HIGH-GRADE AND SPECIALLY DESIGNED FOR STATIONARY, MARINE and THE BETTER CLASS OF ENGINES

SOME OF ITS EXCELLENT FEATURES.

The filler plug is set at an angle, giving ample space between it and condenser for grip of hand. The filler opening is funnel-shaped, with large opening, permitting use of large-spouted oil can; saves both time and oil when filling cup.

The drain valve for the sight-feed glass is directly under the oil-regulating valve, a combination of two valves in one, but operated entirely independent of each other. The position of this drain valve mentioned above protects the oil-regulating valve from being covered with oil and water when draining the sight-feed glass.

The Peerless will feed heavy oils and work well in cold weather, from the fact that the arm passing through the oil body is constantly filled with live steam which keeps the oil always in a liquid condition.



Made in both single and double connection

The POLAR —

The Penberthy Polar Lubricator is built principally for outdoor service, and is specially adapted for portable and traction engines, hoisting engines, steam pumps, etc., on acount of its excellent feeding qualities in cold weather. This lubricator is designed with a sight-feed glass on the same order as those found on the most expensive cups; the feed being oil through water, which shows clearly the exact amount of oil being fed to the engine. Polar Lubricators are made of the best steam metal, are carefully assembled and tested, and will give the best of satisfaction.

Write for Our Ready Reference Catalog To-day.

Penberthy Injector Co., Limited, WINDSOR ONT.

Increased Distributing Capacity In Mechanical Rubber Goods

The demand for highest-grade mechanical rubber goods has increased so persistently during the last few years as to make rapid and efficient service particularly appreciable.

This company's colossal manufacturing facilities have kept pace with the growth in the use of such famous "Mechanicals" as:

Peerless Rainbow Belting, Rainbow Packing, Sawyer Canvas Belting, Eureka Fire Hose, Giant Steam Hose, Rinex Soles, Supremo Conveyor Belting, Hold-tite Friction Tape, Peerless Honest John Packing, Relio Belting, Usco Radiator Hose. Rainbesto Packing, Buckeye Splicing Tape, Four Ace Seamless Belting, Paragon Fire Hose, Anaconda Tender Hose, Peerless Air Hose, Kold-Pak Jar Rubber, Revero Garden Hose, Spring Step Heels, Giant Seamless Belting, Giant Suction Hose, Usudurian Packing; as well as, hundreds of miscellaneous rubber items, such as rubber soles and heels, rubber tiling, matting, mats, plumbers' supplies, rubber thread, rubber toys and golf balls.

To co-ordinate supply with distribution, the United States Rubber Company has now established branches in the principal cities. These, with the strategical location of its factories in the big centres East and West, enable the largest rubber manufacturer in the world to serve the public on a scale equal to its mighty manufacturing capacity.

In this way a nationalized service has been provided to meet every requirement of the people.

As an absolutely certain means of identification, all United States Mechanical Rubber Goods will bear, in addition to their own famous brand names, the great seal of the United States Rubber Company — the hall mark of quality.

Every branch of the Mechanical Goods Division of the United States Rubber Company thus becomes Mechanical Rubber Goods Headquarters with increased capacities for distribution.

Not a War-Time Slogan

"Annual Sales over $5,000,000" — this is not a war-time slogan. This immense sale of Hoyt Metals belongs to normal times as well as war times, when babbitting metals of the **Hoyt High Quality** are in extraordinary demand.

Power house plants in all quarters of the globe (enemy countries excepted) are users of Hoyt Babbitts.

For Engines, Pumps, Mills, Pulp Machinery, Planing Mills, etc., it has no equal.

Order from your dealer—if he can't supply, have us ship you a 25-pound trial box direct.

HOYT'S FROST KING

A first-class all-round Babbitt. It will not only take care of high speed, but will stand up to heavy work in an extraordinary way.

For saw mills, planing mills, threshing engines, traction, rolling mills, pulp machinery, and all classes of stationary engines, it is without equal.

HOYT'S NICKEL GENUINE

Is designed especially for use in gas engines, gasoline engines, and all classes of marine engines and is especially adapted for automobiles. For heavy duty high speed work is probably as perfect as an alloy can be made.

Boiler Scale Costs More than Boico

Think of all you pay for it—Boiler scale. In the course of a year you pay tons of coal, and all the time it acts as a check to power efficiency. Like corroding rust, it slowly but nevertheless surely shortens the life of your boiler.

The cost of Boico is trivial compared with all you pay for scale. For Boico positively removes boiler scale and absolutely prevents further formation. It saves fuel, oil and packing. It will not carry over in the steam; it will not cause foaming or priming, and it is guaranteed not to injure packing or valves in the slightest. **Write for free trial.**

Copper Asbestos Boiler Gaskets

are made of copper, with pure asbestos cord-filled corrugations. They put a stop to leaks in pipe lines, for they never blow-out and never stick.

Tip-It Patent Welding Process

gives you tools whose shanks are carbon and whose cutting tips are high-speed steel. A money-saver!

Get in touch with us to-day!

Anti-Clinker Shell Bar Grates

insure more heat from much less coal. Built on a scientific air-draft principle, fully 50% of the total surface air space, they provide ample air to command perfect combustion, adding as much as 25% more heat to the fuel gases and so preventing clinker formation. Moreover, Anti-Clinker Shell Bar Grates cannot twist or warp, and they're easily cleaned.

THE OLD FASHIONED WAY

Money Going Up in Smoke!

Here is a man stoking in the old-fashioned way. He is a good fireman! He'll get up steam all right but the cost is at least 15% more than it needs to be. What is wanted here is a modern stoking equipment—the

JONES UNDERFEED STOKER

The "Jones" equipment automatically maintains a uniform steam pressure; it responds instantly to load fluctuations and will make 85 tons of coal go as far as 100 tons would go with the man with shovel.

Simplest stokers built: no parts moving in contact with the fire; no grates; no losses through bars; no smoke.

A big paying investment for the large or small plants. Hundreds of plants are effecting savings from 15 to 25 per cent.—plants similar to [illegible].

Pay you to investigate the ability of the **Jones Underfeed Stoker.** We'll gladly put you in touch with a number of users.

Jones Underfeed Stoker Co.

Limited

37-41 Britain St. **Toronto, Ont.**

THE JONES MODERN WAY

CYCLONE Shaking and Dumping Grates

Cut Fuel Costs!

You can burn any grade of hard or soft coal or screenings and get maximum results with CYCLONE Shaking and Dumping Grates. Burning of low grade fuel and getting proper combustion is made possible by 60% air space and 90% underdraught. No ashes, no clinkers, no waste with Cyclone Grates.

Our trial proposition is convincing. We are prepared to install our grates for a bona-fide company on 30 days' trial. Easy and convenient to put in. In these days of coal scarcity Cyclone Grates prove a splendid investment. Get in touch with us.

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compressors

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction.* Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under any unforeseen strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satistactory operation, but practically *eliminates expensive shut-downs.* Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring oiled bearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

The Publisher's Page

TORONTO APRIL. 1918

INCORPORATED MAY. 1887.

INCORPORATED AT OTTAWA JUNE. 1917.

Mr. E. G. Newton,
Manager,
Power House,
153 University Ave.,
Toronto.

Hamilton, Feb. 12, 1918.

Dear Sir:

In answer to your enquiry as to whether the Canadian Association of Stationary Engineers have added to their membership through the advertising which has been appearing in POWER HOUSE I take great pleasure in stating that our membership has increased to a marked degree.

As a matter of fact we have received enquiries from all over Canada and I have received one letter from the trenches in France, and I can truthfully state that I have had difficulty in keeping up with my correspondence as a result of the enquiries which have been pouring in.

As you know, this advertising has been running in POWER HOUSE for seven or eight months and judging by results already secured our year's campaign will net us a great many new members. A feature which speaks well for POWER HOUSE and which is significant is the fact that enquiries have been from good engineers in first-class standing and in charge of good plants.

Speaking for other engineers with whom I have talked, as well as for myself, I can say that POWER HOUSE Buyers' Directory is invariably consulted when supplies are needed. If the average engineer does not mention POWER HOUSE when writing to advertisers it is probably because they do not think it necessary or they may forget to do so. Of one thing I can assure you and that is our members certainly prefer goods advertised in POWER HOUSE to any others.

I would like to mention the exchange of views among the engineers through the medium of POWER HOUSE. If Canadian engineers would use the pages of POWER HOUSE to exchange their ideas more one among the other, they would be not only benefiting themselves but would be helping those less fortunate. We have in Canada engineers who will compare with any engineers in the world and I feel that there should be a greater exchange of ideas and I am taking this up with our members at once.

Wishing you all success and assuring you of our continued co-operation, I am,

Yours faithfully,

Jno H Hale

Executive Secretary,
Canadian Association of
Stationary Engineers,
Hamilton, Ont.

To Manufacturers

Meet Mr. Hale, Executive Secretary of the C.A.S.E. Live wire and all-round good fellow. Look at his frank, open smile! Read his frank, open message. There's a whole lot in it for manufacturers of power equipment and supplies. A whole lot.

P.S.—We used Mr. Hale's photograph some months ago in connection with an article which he contributed. That's how we happened to have it.

To Engineers

We would like every engineer to read Mr. Hale's letter reproduced herewith, especially the fifth paragraph. What's the use being a "brother engineer" if you don't extend the brother's helping hand to *as many* engineers as you possibly can? By sending to POWER HOUSE your ideas, your pet schemes for overcoming difficulties, the solutions you have worked out for yourself, you will be extending a glad and helping hand to hundreds. That's the way to apply forced draft to a good idea!

JOHN H. HALE

Electricity as a Factor in Modern Rolling Mill Operation

By L. Rothera

The advantages of electric drive for rolling mills are so well known that in many cases only the cost of changing over and the trouble encountered in obtaining equipment prevent the remodelling of mills doing widely different classes of work. The present article deals with the engineering problems connected with the installation of electric drive.

THE electrical horse-power used in British steel and metal works is now well in excess of 300,000. Taking, perhaps, the greatest stronghold of the steam drive, namely, mills with heavy reversing duty, it is interesting to note that whilst in 1914 only four such electric drives were in operation, of which two were of comparatively small size, there have since that date been no fewer than nine equipments put in hand, according to Mr. L. Rothera in a paper read before the Manchester Association of Engineers, with powers at the mill ranging up to 20,000 horse-power, and most of the big steel manufacturers are giving very serious consideration to electrical plants of this description, and a further number would have been installed had it been permitted.

Power Required

In Figs. 1, 2 and 3 respectively are shown the form of power demand in the case of a heavy sheet mill, a wire rod mill and a section mill rolling joists, and a study of these curves gives a measure of what the prime mover may be called upon to do. It must be borne in mind also that apart from the power requirements there have to be taken into consideration the needs of the mills as regards speed control, and the complications introduced by the lack of uniformity of the power systems on which the motors have to work. It is possible for the makers of electrical machinery to point to a very wide series of equipments which have satisfactorily and efficiently met the varying demands, and proved the entire adaptability of the electric motor to meet the most arduous conditions.

The advantages which can be claimed for the electric drive have been stated

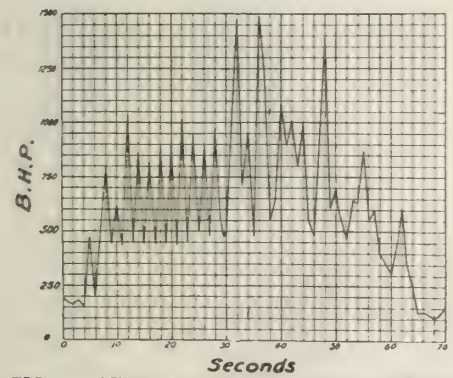

FIG. 1. CURVE SHOWING POWER DEMAND OF HEAVY SHEET MILL.

time and again, but it is impossible in a paper dealing with this subject to avoid some reference to the reasons which tend to its adoption, and a short summary of them is as follows:

(1) Economy of working, i.e., reduction in cost per ton of material rolled. This results from a number of causes, such as the great rapidity of working and high efficiency of the electric plant at all loads, from light load to the maximum permissible overload. This economy of working persists throughout the whole life of the plant, as electrical machinery maintains its efficiency unimpaired independently of the time during which it has been at work.

(2) Reduced space taken up. Partly on account of the small size of a motor as compared with its output, and partly due to the possibility of placing the motor in the most convenient position, without having to consider the run of steam pipes or the relative position of the boiler-house.

(3) Ease of control, such as stopping, starting, or varying the speed of the drive.

(4) Constant check on the power consumed. A recording instrument gives immediate information as to an undue consumption of power, thus enabling adverse circumstances to be promptly noticed and remedied.

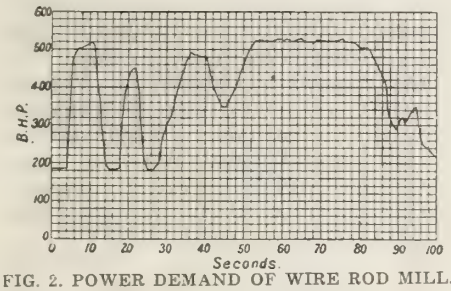

FIG. 2. POWER DEMAND OF WIRE ROD MILL.

(5) Increased output from a given plant. This results from the large overload capacity and constant speed of the electric motor under all conditions of load.

(6) More uniform drive. The turning moment of a motor is constant for any position of the rotor, whereas a steam engine turning moment fluctuates, depending on the position of the cranks.

(7) Smaller initial cost. This is particularly the case where electric power is available from a neighboring central station, and, on the other hand, boilers would be required in the event of a new steam engine being put down.

The above represent only the main points that can be put forward in favor of the electric drive, and there is a very large number of additional advantages which, whilst small in themselves, serve to advocate its use. Amongst these may be mentioned the cleanliness of the drive, the small cost of upkeep, reduction in oil consumption, information easily available as to the actual demand on the prime mover for varying classes of material and draughts, and many others.

The advantages carrying the greatest weight vary with the varying conditions of each equipment, and when any new scheme is under consideration, a full knowledge of such factors is essential for a true estimate to be made in this respect. Take, for instance, the saving

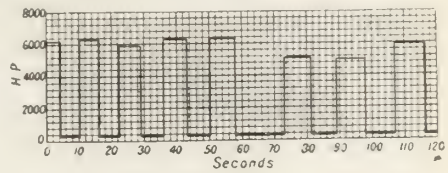

FIG. 3. POWER DEMAND OF SECTION MILL.

of space; this naturally is of greatest importance when a plant is installed in the centre of a town where it is impossible to extend, and every square foot of ground is valuable. Such an instance occurs in the Birmingham district, where motors have been installed under the floor, and also on platforms under the roof to leave the floor space clear for mills. Where a new plant is being laid out with ample ground at command, this argument has not nearly so much weight.

Equipment for Tin Bar Rolling

The layout of the motor house for driving a 30 in. reversing finishing mill for tin bar rolling is given on page 142.

The motor in this case was designed to give a maximum peak horse-power of 5,300, and is direct coupled to the mill, the speed being variable in either direction between 0 and 180 revolutions per minute. The cooling of such a machine, owing to the periods at which it is at rest, is not so satisfactory as in the case of a continuous running motor, and, consequently, a forced draught is blown into the machine by means of a motor driven fan, to produce the necessary cooling. To prevent an undue amount of dust settling on the windings of the machine, which ultimately might cause trouble, a filter is introduced which cleans the air before it reaches the motor.

Equipment for Reversing Work

When designing an equipment for reversing work, two main factors have to be taken into consideration—first, the maintenance of a steady demand from the supply in place of the rapidly recurring peaks called for by the mill, which may exceed 20,000 horse-power, and, secondly, the reversal, in a simple manner, of a mill motor, the rotating portion of which may weigh up to 120 tons.

These two difficulties are met by the introduction of a motor generator flywheel set, the fly-wheel acting as a reservoir of energy. The motor driving the flywheel is calculated out on the average load taken by the mill over a period, and may be of ¼ or even 1/6 of the horse-

power of the mill motor, depending on the class of work being done, the difference in power between the demand of the mill and the power of the fly-wheel motor being either given out by, or stored up in the fly-wheel, as the power demand is greater or less than the average.

The reversal of the motor is done very simply by altering the direction of the

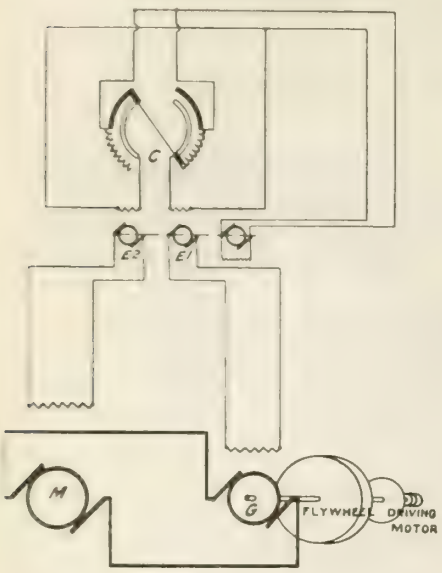

FIG. 4. DIAGRAM OF CONNECTIONS.

current supplied to its armature by the generator of the fly-wheel set, the control of the latter being done by varying its field current in strength and direction. Thus, no armature currents, which may exceed 8,000 amperes, need be controlled.

As the use of this type of equipment is coming rapidly into prominence, a short description of the method of control is, perhaps, not out of place.

The operator for the mill is on a platform raised over the live roll track on the incoming side of the mill, and the whole of the control of the speed and direction of rotation of the mill motor is done by means of a lever moving backwards and forwards in a straight slot. The centre position of the lever corresponds to a state of rest of the motor, and a forward or backward movement gives a rotation in the one direction or the reverse.

This procedure is similar to that adopted in the case of a steam drive, but where it differs in an important particular is that each position of the lever corresponds to a definite speed of the mill motor independently of the power being given. Thus, under no circumstances can the speed of the motor exceed the maximum for which it is designed, and the racing so noticeable with a steam engine when the metal leaves the rolls is entirely avoided, and the attendant stresses produced eliminated.

It may be mentioned also at this point that the stored energy in the rotating parts of the motor is, on reversal, not wasted as in the case of an engine, but restored to the fly-wheel and thus rendered available for the next pass.

Method of Control

The function of the control lever is to vary the field currents of a small motor generator set embodying two generators, the armature output of which is used for exciting the fields of the variable voltage generator and the mill motor respectively. With the control lever in the central position, the field current in the exciter supplying the variable voltage generator is at zero, whilst the field current in the exciter supplying the mill motor is at maximum. Thus you have the condition that the mill motor is fully excited whilst the variable voltage generator is at zero voltage. A forward or backward movement of the lever serves to raise the voltage on the generator supplying the mill motor armature by acting on its exciter, and the speed of the motor corresponds to the voltage thus applied and its direction of rotation to the design of the voltage. This raising of the voltage continues until the maximum speed is reached, at which the full torque is required, after which a further movement of the lever weakens the mill motor field through its exciter and the speed of the motor increases to its maximum value. Constant horsepower, that is, reducing torque with increasing speed, is given throughout this latter portion of the speed range.

Fig. 4 shows in skeleton the diagram of connections for the plant, E 1 and E 2 representing exciters of the variable voltage generator and mill motor respectively, C being the main controller and M and G being the mill motor and variable voltage generator.

This method of control, whilst somewhat cumbersome to explain, is very simple in practice, as the only currents to be controlled are those flowing in the fields of the small exciters, the value of which in this instance represents only 1/3 of 1 per cent. of the full-load current of the mill motor. The controller itself is consequently of very small dimensions, and takes a form not widely different from the well-known face-plate type crane controller. In earlier plants the control was carried out by varying the fields of the mill motor and variable voltage generator themselves, but this entailed the use of somewhat complicated cantractor gear, which is avoided under this later arrangement.

The fly-wheel motor generator set consists of an 1,800 horse-power 3-phase induction motor, a 30-ton 12 ft. fly-wheel, and the variable voltage generator mentioned above, the working speed varying between 500 revolutions per minute and 390 revolutions per minute.

The set is carried in four bearings and mounted on a combined bed-plate, the fly-wheel bearings taking half the weight of the machines, which are placed one on each side of it.

The Fly-Wheel

An interesting feature of this plant is the type of fly-wheel employed. To keep the weight of the wheel a minimum whilst embodying at the same time a large stored energy—the value of this latter being 100,000 horse-power seconds—it is necessary to use a fly-wheel with a very high peripheral speed of the order of 20,000 ft. a minute.

Fig. 5 shows a cross-section of the wheel, and indicates the method of bolting up. This design lends itself very easily to perfect balancing, which is essential for satisfactory running, an out-of-balance on the rim of 1 lb. exerting a pull equal of 500 lb. To reduce the windage losses to a minimum, the sides of the spider are enclosed by polished steel plates, and a cover surrounds the outer rim of the wheel for the same purpose. when first experimenting with high-speed fly-wheels, a test was made to see whether any considerable saving in windage loss could be obtained by running the fly-wheels in vacuo, but it was found that more power was used in maintaining the vacuum than was saved by adopting this practice.

Special means are adopted for lubricating the fly-wheel bearings, oil at a pressure of about 300 lb. to the square inch being forced in under the shaft by means of small gear pumps, one for each bearing. These pumps are driven by belts from the fly-wheel shaft, but on account of the importance of maintaining a continuous supply an alternative set of motor-driven pumps is provided, which are used for starting-up purposes, and also as a stand-by to the belt-driven pumps.

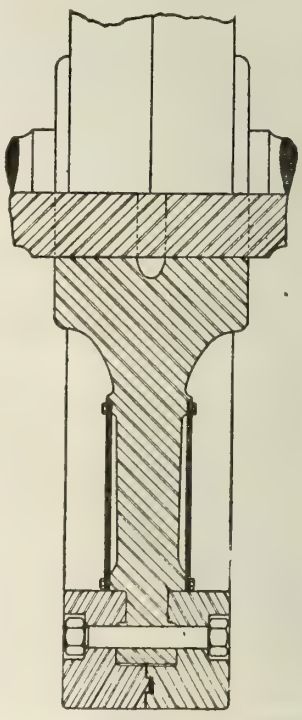

FIG. 5. SECTION OF FLYWHEEL.

The oil on its return from the bearing is first passed through a filter and then through a cooling tank before being used over again. In addition to this forced lubrication system, oil rings are provided, which serve the purpose of keeping the plant running for a short time in the

event of the failure of the forced lubrication.

The interchange of power from and to the fly-wheel is brought about by means of an automatic slip regulator. This consists of a water resistance, the value of which is altered by raising and lowering suitably shaped metal plates in the tanks containing the water. The movement of the plates is brought about by a so-called torque motor, which can be seen in the illustration. This machine is similar to an ordinary induction motor, but the rotor is prevented from moving by the restraining force of the plates. The weight of these serves to counterbalance the tendency of the rotor to move at such times as the normal current is being taken by the motor driving the fly-wheel set. When a piece of metal enters the rolls there is a heavy demand for power from the fly-wheel set generator, which power would, under ordinary circumstances, be reflected in the power given by the motor driving it. In the present instance, however, as soon as the current taken by the motor tends to rise, the torque motor, which is controlled by this current, exerts a larger turning moment and raises the plates, thus inserting an increased resistance in the rotor of the driving motor, which, consequently, falls in speed, and the make-up power between the demand of the mill and the normal power of the motor driving the fly-wheel set is given out by the fly-wheel. When the metal leaves the rolls the demand from the mill immediately falls below the normal and the reverse action takes place: the weight of the cable connections leading to the motor and they are lowered into the liquid, thus reducing the resistance in the rotor, and the motor speeds up, restoring energy in the fly-wheel.

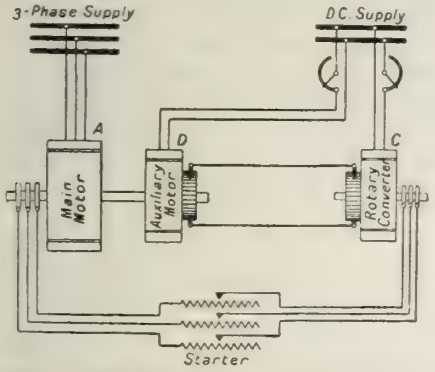

FIG. 6. DIAGRAM FOR 16 IN. MERCHANT MILL.

A speed variation of 20 per cent. is usually allowed on the fly-wheel set, thus rendering available for useful work 36 per cent. of the total stored energy of the fly-wheel. The torque motor is operated by a series transformer mounted in the cable conections leading to the motor of the fly-wheel set, and by having tappings on this transformer a simple adjustment varies the power taken by the motor. This is of service when rolling lighter material, as the average demand from the power station can be reduced proportionally, and in the case of the plant in question, one-half the normal power has successfully been used on certain classes of material.

Instrument

Mounted alongside the control lever is an instrument pillar which serves to give the driver full information as to the operation of the complete set. An ammeter indicates the power being given at any moment by the mill motor, whilst an indicator simultaneously gives the speed at which this motor is revolving. Three lamps which light up at different speeds of the fly-wheel set give information as to the reserve power in the fly-wheel, and if the lamp corresponding to the lower working limit of the set comes in, it is necessary to roll slowly until such time as the fly-wheel set has regained its speed, as otherwise the mill demand would be reflected on the supply and the driving motor would be overloaded.

Motor Drive for 16 in. Merchant Mill

The illustration, Fig 6, represents the motor drive for a 16 in. merchant mill for rolling general sections, with an output per shift up to 140 tons. The motor installed was rated for a normal continuous output of 1,000 horse-power with an overload capacity of 25 per cent. above that figure for two hours, and 100 per cent. momentarily.

The mill consists of three stands of rolls working three high, of which two stands are employed when rolling angles, and three stands when rolling rounds, and is fed from a continuous heating furnace within a short distance of the incoming side. Power-driven live rolls work on both the incoming and outgoing sides of the mill.

To meet the various classes of work dealt with in a merchant mill a variable speed is essential, and the question arose as to how this could best be obtained with only a three-phase power supply available. It was decided finally to to adopt a composite set which, whilst taking power from the supply, gave all the characteristics of a D.C. motor, such as easy and efficient speed control, constant horse-power, i.e., increasing torque with reducing speed, and a drop in speed from no load to full load without loss of efficiency, so that a fly-wheel could be beneficially utilised.

A number of other drives of this type have been employed throughout the country with good results, but in modern practice it is now more usual to install rotary converters connected to the three-phase mains, which generate direct current which is applied directly to a direct current motor on the mill.

Fig. 6 gives a diagrammatic arrangement of the plant and its connections.

The power, which at the lower speed would normally be wasted in the rotor resistances, is taken to the slip-rings of

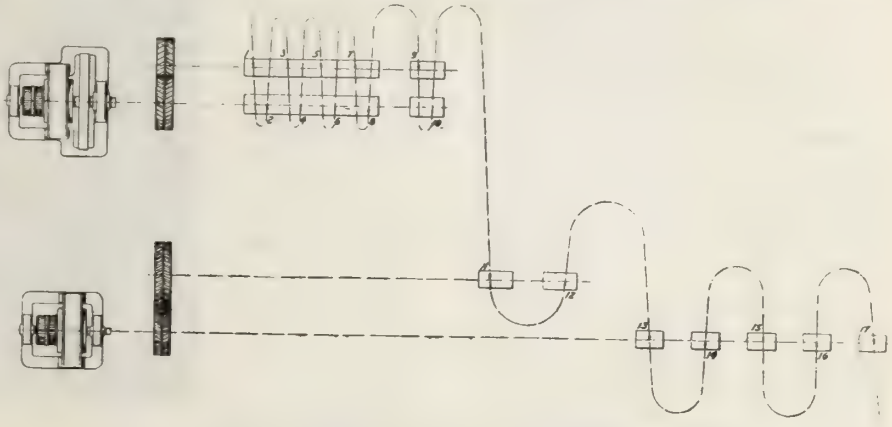

FIG. 7 LAY-OUT FOR A 7-IN. WIRE ROD MILL.

a rotary converter C, and is there transformed to direct current power which is delivered back to the direct current motor D, which is coupled directly to the induction motor. Consequently, the reduced horse-power of the three-phase motor with reduced speed is compensated for by the increased power of the direct current motor, the horse-power output of the set remaining constant independently of the speed.

The motor set is designed for a constant output of 1,000 horse-power at any speed between 75 and 150 revolutions per minute, the lower speed and increased torque being used when rolling the heavier sections. A flexible coupling mounted on the motor shaft extension couples up to a 40-ton 14 ft. 6 in. diameter fly-wheel, which is connected directly to the mill. The speed control of such a plant is carried out by altering the field of the direct current motor D. by means of a shunt regulator mounted on the switchboard, and by having this auxiliary motor compound wound, a fall in speed is automatically produced between no load and full load, thus enabling the fly-wheel to give out a portion of its stored energy when the peak loads occur.

Drive for 7 in. Wire Rod Mill

A diagram of the layout for a 7 in. wire rod mill is given in fig. 7. The mill consists of two sets of rolls, the bolting and finishing rolls respectively, and these were originally driven through belts from the two engines mentioned above. When the new drive was installed the belting was done away with and two motors were directly coupled, one to the bolting roll train and one to the finishing roll train. The bolting rolls are of the double two-high type with repeaters

behind the rolls, and the finishing train is three-high, and the wire is looped by hand in the usual way with this type of mill.

Before the size of motors and generating plant was definitely determined, careful tests were taken on the existing steam engines as a guide to the power required. This was necessary, as the drive represented the first example of a wire mill to be electrically driven in this country. An ample margin was allowed on the power so obtained to cover the greater output it was proposed to roll in the mill, and the motors finally installed were of 400 horse-power for the bolting rolls and 550 horse-power for the finishing rolls. The generating plant was designed for an output of 750 kilowatts at 440 volts direct current, the turbine being of the mixed pressure type.

The incoming billet for the bolting rolls is about 2 in. square, and leaves this train of rolls with an area of about $\frac{1}{8}$ square inch. This passes straight forward to the finishing rolls, and as many as ten passes may be occurring simultaneously. The normal size of rod finished is about 3/16 in. in diameter.

The 2 in. billet enters the bolting rolls with a length of about 3 ft., and heavy draughts are taken on the first few passes, resulting in short but heavy peak loads. The average demand for power throughout this period is comparatively small, and the motor is designed from the usual point of view, viz., that of the average demand rather than that of the peak demand. This has two advantages, the first and most important being that

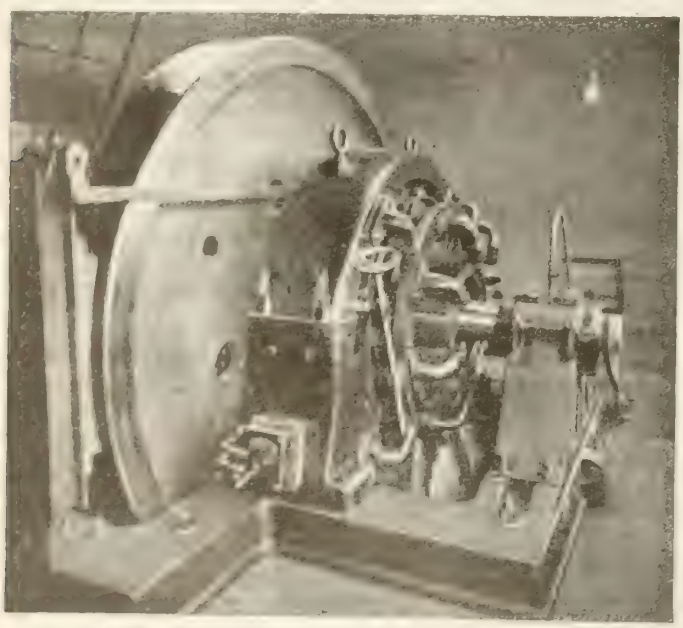

FIG. 8. FLY-WHEEL FOR WIRE ROD MILL.

the peak loads required from the supply are reduced in value and lengthened in time, thus giving a much more favorable condition for efficient working. Secondly, the capital cost of the plant is reduced. The difference in power between the average demand and the peak demand is obtained from a fly-wheel inserted between the motor and the mill, which automatically has its speed reduced during such periods of load.

A cast steel fly-wheel, about 15 tons in weight, 12 ft. 6 in. in diameter, was supplied in the present instance and arranged in the manner seen in Fig. 8.

The armature of the motor was mounted directly alongside the fly-wheel and the whole supported by two solid bearings carried on an all-round bed-plate. This method has the advantage of considerably reducing the overall length of the drive and of avoiding any form of coupling between the motor and the fly-wheel.

The motor, to meet the varying classes of work, was designed with a speed range between 190 and 270 revolutions per minute, at full load, and a compound winding automatically gives a fall in speed from no load to full load, so that the stored energy in the fly-wheel may be utilised.

To ensure good commutation under all conditions on load, a compensating winding is added to the field to neutralize the heavy armature reaction which occurs on peak loads. This practice, whilst adding slightly to the capital cost involved, is fully justified by the improved commutation which results.

A director mounted on the frame of the machine is used for shunting a portion of the current flowing round the compound winding, and enables the fall in speed between no load and full load to be adjusted at will, thus on light material the average speed of the motor can be kept up by using a less drop in speed.

The finishing mill motor—Fig. 9—is also of the variable speed type, the range being 400 to 550 revolutions per minute at full load. No fly-wheel was employed in this case, as the peak loads, owing to the long length of material rolled, persist for an appreciable period, and an equalising effect could only be obtained by having a fly-wheel of a

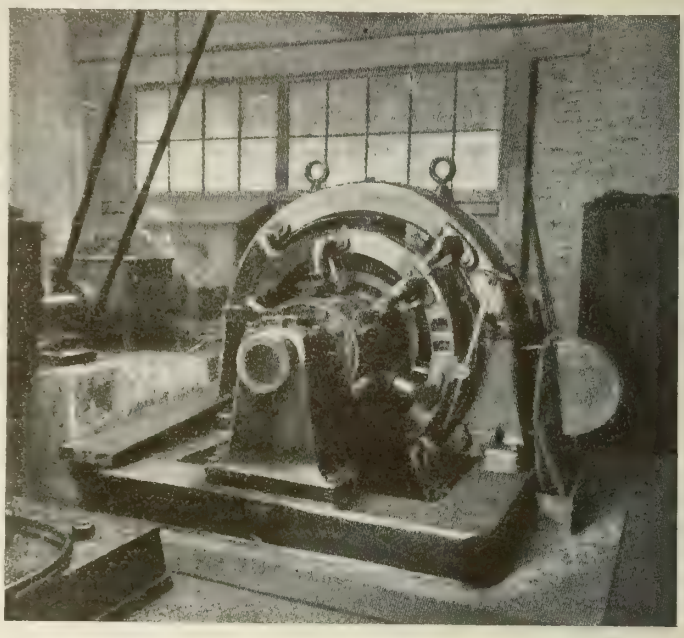

FIG. 9. MOTOR FOR FINISHING MILL.

weight which would prove a non-commercial proposition. The results obtained from this drive were so satisfactory that the conversion of the remaining plant has been proceeding steadily since that date, and three additional motor drives have been installed. The mills are engaged on general merchant work which, from its variety, necessitates, for efficient rolling, a wide range of speed on the motor. This in turn renders the employment of direct current motors almost obligatory, and for this reason the generating plant was of the direct current type.

It may be stated generally that direct current motors have proved themselves more suitable than three-phase motors over a wider range of work, and for steel works practice it would appear as though such motors would be the more widely adopted in the future.

Methods of Driving

In the above-mentioned examples the motors have been direct coupled to the mills, and have run at the same speed. This practice is one which can be recommended as being the most efficient, and, at the same time, the most reliable as any form of transmission, whether gear or ropes is omitted. Such direct coupled motors have been used even for sheet mill drives where a speed of, perhaps, 30 to 35 revolutions per minute has been necessary, and although the adoption of such a slow speed increases the capital cost of the plant, yet in most instances the efficiency saving can be shown to justify such a drive, particularly when taken into conjunction with the elimination of the upkeep of ropes or gears, and the extra cost involved, when considered as part of the capital cost of the com-

plete mill, represents only a fraction of the total.

In certain cases, and particularly where an existing drive has to be converted, it may be necessary to have some form of transmission drive, such as gear or rope, the most usual reason for adopting such transmission being the desire to put down the electrical plant without stopping the mill. It is also usually somewhat less costly to have high-speed motors with some form of reduction to the mill.

FUEL SITUATION IN WAR TIME*

By T. Britt†

NEVER in the history of the world has coal been of such vital importance, it is the life-blood of the nations engaged in this unfortunate world-wide war, and the success of the Allies is very largely dependent upon its increased production and careful conservation.

It was customary in former years to send the surplus coal produced in Eastern Canada to the New England States and from Western Canada to the Western States. Central Canada and that part west of the Great Lakes and as far as Brandon being supplied with American coal.

The total production of Canadian coal prior to the war was 15,000,000 tons per annum, and in the United States between 500,000,000 and 600,000,000; the latter being the production for 1916.

During the year 1917 Canada will produce nearly 2,000,000 tons less, and the United States approximately 50,000,000 tons more than in 1916. But as the increase in consumption is approximately 100,000.000 tons, there is a shortage of 50,000,000 tons to be made up by elimination of wastage.

Sending Eastern and Western Canadian coal to the United States and American coal to Central and part of Western Canada was with the object of sending coals by the most suitable rail traffic routes and waterways, and providing more even distribution.

If the Eastern Canadian coal was moved west it would be against the current of traffic to Fort William, and if Western Canadian coal was moved to Eastern Canada it would put onto railroads the burden of transporting the longest distance on the American continent.

What Is Expected of Us

The United States Government has been very considerate towards Canada, and will continue to be so, the intention being to treat Canada on an equality with any state in the Union, but, while doing this, they expect and insist that we do the same as they doing, viz., inaugurate a campaign for the intensive conservation of fuel.

It is not the purpose of this paper to point out in what way our share of the deficiency is to be made up, it being principally a matter of good engineering and true fuel conservation in the boiler-room.

Canadian railways have already reduced their annual passenger train mileage by 10,000,000 miles, and have further decreased the fuel consumption by lengthening out the times of other trains and by eliminating fast freights and instead running trains with full tonnage, and by equipping locomotives with superheaters, and the best known modern means of lessening fuel consumption.

The Canadian Pacific Railway has been helping the cause by breaking up and using old ties for fuel—this even at considerable expense of labor, train service, etc., gathering and handling.

The United States have also made a start in reducing their passenger service and loading their trains to the tonnage limit, thereby affecting a saving of several million tons of coal per annum.

Action Advocated

I think that we should go further, and I would submit to the consideration of this club the necessity of the mechanical members getting together and inaugurating an active educational campaign among the firemen, both locomotive and boiler-house men.

To my mind this should not be done by printed instructions but by actual illustration by competent firemen. While it is all very well to write a fireman and tell him what he should do, it is far more educational for a competent instructor to show how it should and could be done.

There is a lot of fuel wasted by automatic stokers not receiving intelligent attention from the fireman. The stoker itself when in proper working order will do all that is required of it, but there are, however, occasions when it will not do what it is supposed to, it is then that a properly instructed fireman will give necessary assistance with a consequent saving in fuel.

The majority of our passenger trains, particularly the sleeping cars, are overheated—it being largely left to the discretion of the colored porter as to what is considered a comfortable temperature, the result is that the temperature is kept up to a point that means comfort for the porter and discomfort for the passengers.

Our houses are being maintained at an unhealthy temperature. Pneumonia takes a little more than one man in eight, and therefore it grasps from tuberculosis the grim honor of killing the most human beings.

Man is a marine animal, seven-eighths water, he needs cool air and moisture around him, overheated dry air makes him susceptible to disease, and in a temperature of over 68 degrees it is difficult for men and women to exist healthfully.

If the people can be taught to live in this temperature, the number of pneumonia victims wil shortly decrease. Fresh, cool, moist air is the foe of pneumonia, and persons who keep their houses cool and breathe pure fresh air have no fear of it.

Normal Temperatures

Celebrated doctors have decided that 65 degrees is ample for persons in robust health actively engaged, 70 is too much, with 68 we have a fair healthy average.

Many activities which involve large consumption of fuel, and many methods of using this fuel, which are practically legitimate in time of peace, will be found susceptible of changes which involve very slight sacrifices of material interests but afford opportunities for considerable saving of fuel.

We have in the past been an extravagant people in the use of fuel, and as the war continues it will be necessary to get down to bedrock in the matter of fuel economy.

Manufacturers of non-essentials should during these war times voluntarily forego the manufacturing of such articles before being compelled to do so by Government direction.

Wherever possible water power should be utilized. In wooded districts, of which there are several in Canada, wood should be utilized wherever possible. One cord of hard wood is equal to one ton of coal, and one ton of coal is released for use in war work for every cord of wood substituted. It will be found that there is a vast quantity of dead wood in many sections of the country. It will also be found that the supply of wood in many communities is sufficient for domestic purposes in these parts. This wood in many instances is destroyed as waste, and its conservation will not only serve the patriotic purpose of conserving coal needed to win the war, but will also prove a measure of economy to the user.

In certain districts prison labor might be used as a means of cutting and collecting wood, where, of course, the labor of the prisoners could be utilized without interference with free labor.

As a matter of fact the one practical and needful thing to-day is to save coal in order that our transportation lines and munition plants may have sufficient to carry on. It may be patriotic and a certain amount of pleasure may be derived from singing "Keep the Home Fires Burning," but the saving of one ton of coal is of more practical benefit towards assisting the boys in the trenches than the singing of one hundred songs.

*A paper read before the Canadian Railway Club. Montreal, Jan. 8, 1918.

†General Fuel Agent, C.P.R., Montreal.

THE Advisory Council for Scientific and Industrial Research of Great Britain has made special grants for the purpose of research into the questions of the use of better methods of heating and improvement in the ventilation of dwelling rooms, and of atmospheric pollution, the causes for producing it, its results on public health, buildings, etc., and the value of various means of counteracting it.

Electricity and Hydraulics

PRINCIPLES AND OPERATION OF MODERN ELECTRICAL EQUIPMENT—II.

By A. M. Pere.

IN the study of the principles governing the flow of energy in the form of electricity from the source of supply an interesting illustration presents itself. Several of these principles may be compared very readily with those occurring when the flow of liquids is observed.

When the transfer of electrical energy takes place there must be a source of supply, a conducting medium, and a means of utilizing the energy transferred. The same three conditions apply to the transmission of power by a hydraulic system, or one in which the medium used is water. As will be seen, the analogy can be further extended to take in the facts relating to flow, such as quantity, pressure and rate of flow. One particular limitation must be imposed on the electrical circuit—that it be closed upon itself and have neither beginning nor end, like the circumference of a circle.

Hydraulic Analogy

Fig. 1 shows an imaginary arrangement which might be used to transmit power by means of a pump, a pipe line, and a water motor or water wheel, which we will suppose to be full of water, so as to form a completely water-filled system.

If the valve shown be closed and the pump started up, it is readily seen what relations the pressures in the pipe line will bear to each other, for the pressures between the points A to B, C to D, and E to F will all be equal to each other, and the pressure between the points G to H will be equal to zero.

The gauges shown are supposed to be made of glass filled with mercury and connected up in such a manner that one end of the U-tube is in communication with one side of the system and the other end with the other side. A difference in pressure will indicate its presence by altering the levels of the mercury until the difference in weight will counterbalance the difference in pressure.

There will, of course, be no flow of water through the system, but a pressure will exist between the outgoing or pressure line and the suction line. No power would be transmitted, and if the pump were of the centrifugal type and of the proper design very little power would be needed to maintain the pressure, and that used would be dissipated in the form of friction and heat in the pump itself.

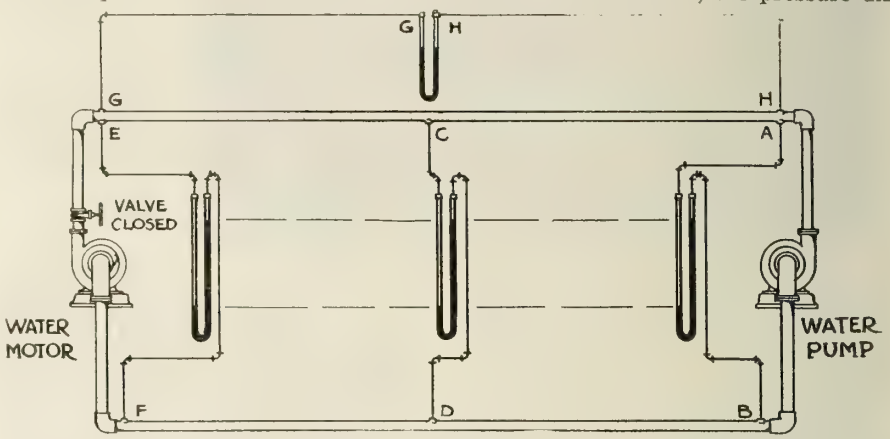

FIG. 1. ILLUSTRATING SIMILARITY EXISTING BETWEEN A HYDRAULIC AND AN ELECTRIC SYSTEM FOR TRANSMITTING POWER. THIS ILLUSTRATION SHOWS CONDITIONS EXISTING WHEN THE VALVE IS CLOSED

Hydraulic Pressure Drop

If now the valve be opened so as to allow a flow of water, the pressure differences would alter immediately, as shown in Fig. 2. The pressure existing between E and F would be less than the pressure between C and D, and still less than the pressure between A and B.

This is easily understood when the friction due to the pipe is taken into account, and it simply means that the whole of the pressure exerted by the pump is not available at the point where the power is to be utilized.

When the pressure between G and H is now measured it will be found to be quite an appreciable amount instead of zero as formerly. This difference in pressure is again caused by the friction losses due to the passage of water through the pipe, and, as the flow of water is increased by the further opening of the valve, it will be noticed that this pressure difference will be found to increase in magnitude.

In view of what follows it should be borne in mind that the pressure generated by the pump tends to create a flow of water, and it is only when the proper conditions are found, as when the valve is opened, that the current of water is established.

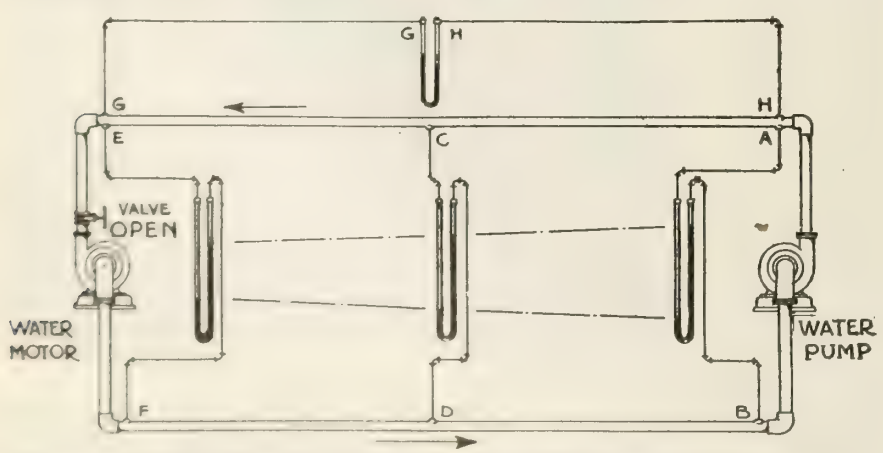

FIG. 2. ILLUSTRATING SIMILARITY EXISTING BETWEEN A HYDRAULIC AND AN ELECTRIC SYSTEM FOR THE TRANSMISSION OF POWER. THIS ILLUSTRATION SHOWS CONDITIONS EXISTING WHEN THE VALVE IS OPENED AND POWER IS BEING TRANSMITTED.

Corresponding Electrical Circuit

In Fig. 3 is shown an electrical circuit similar in its fundamentals to that described above. It also consists of a source of power, two conducting paths and a motor or other means of utilizing the power transmitted.

As before, we will suppose the generator running and the switch shown

near the motor open, so that the motor is not in operation and no power is being transmitted.

When all the meters are read, those across the two sides of the transmission line—that is, those indicating from A to B, C to D, and E to F—will all show the same readings; or suppose voltmeter A B read 110 volts, voltmeters C D and

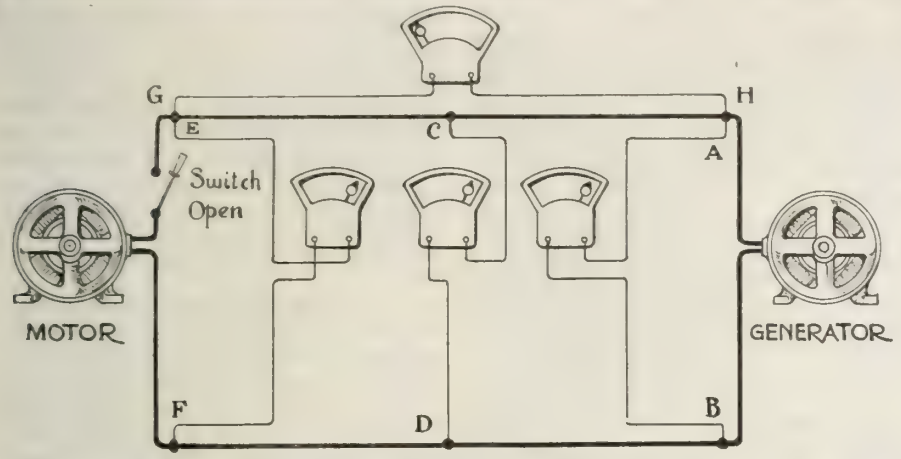

FIG. 3. AN ELECTRIC CIRCUIT ARRANGED IN A SIMILAR MANNER TO FIG. 1. THE SWITCH BEING OPEN, PRESSURE DIFFERENCES CORRESPOND TO THOSE SHOWN IN FIG. 1.

E F would also indicate 110 volts. Voltmeter G H, on the other hand, would show no reading, and would thus indicate that there is no difference in potential between the points to which it was attached.

Now if the switch be closed the motor will start and will deliver power, and a change will be noticed in the reading of all the voltmeters connected with the circuit. (See Fig. 4.)

Change in Voltmeter Readings

Voltmeter A B will indicate slightly less than before, voltmeter C D will indicate less than A B, and voltmeter E F will indicate less than either of the other two; while voltmeter G H, instead of reading zero voltage as formerly, will show a decided reading, whose amount will depend, of course, on the length of line and the characteristics of the circuit.

It will be noticed that the similarity between the behavior of the two systems is very marked, and corresponding to that property of the hydraulic circuit which we term pressure there exists a similar property of the electrical circuit. This property is given various names, such as voltage, potential difference, and electro-motive force (E M F). It is that property of an electric circuit which tends to cause a current of electricity to flow, and, as in the case of the hydraulic system, pressure can exist without a flow of water, so in an electric circuit electrical pressure or potential can exist without causing an electrical current or flow.

The unit of measurement in universal use for this electrical pressure is termed the volt.

Referring to our hydraulic analogy once more, we find another characteristic which may be considered—the amount of water passing a given point in a given time. This quantity is always expressed as a certain amount of water passing a point in unit time, such as gallons per minute or cubic feet per minute.

Rate of Flow

In like manner also there exists a property of the electric circuit—that is, current or rate of flow. This quantity is measured in terms of a unit called an ampere, and an ampere means simply a unit quantity of electricity passing through a conductor in the unit time of one second.

Thus when we speak of so many amperes and so many gallons per minute, we are speaking of properties which, while widely different and having nothing in common, yet convey the same sense to our minds, that of quantity rate of flow.

A question that naturally arises at this stage, and which at times has troubled some students, is, why do we simply say so many amperes and not amperes per second when speaking of current strength or rate of flow, arguing from everyday expressions relating to the flow of liquids, etc.? The answer is, the term ampere includes within itself the idea of time, and it is not correct to say amperes per second in the same way as we say gallons per minute when speaking of rate of flow.

Amperes per second is a term which is analogous to saying feet per second per second, and when an expression such as feet per second per second is used it expresses a change in velocity or acceleration. Later on when the study of alternating current is taken up it will be seen that amperes per second means the rate of increase or decrease in the current flowing, not the measurement of a steady rate of flow.

The Unit of Quantity

Unlike material things, electrical energy can not be measured directly. We cannot speak of it in terms of cubic feet, pounds or gallons, but it can be measured by the effects produced by its presence or flow, and in this respect it is like all other forms of energy.

A definite amount of electrical energy will always produce the same effect or do the same amount of work under the same conditions, and this renders it easy to define a unit of quantity measurement.

In one of the above paragraphs we defined the ampere as meaning the flow of a unit quantity of electricity in the time of one second. This quantity is called the coulomb, and is so chosen that it bears a simple relation to the unit denoting the rate of flow (ampere). The quantity of electricity conveyed by a current of one ampere flowing for the time of one second is called one ampere-second, or one coulomb. Thus when electricity flows at the rate of one ampere during the time of one hour the quantity of electricity which has flowed past any given point in the circuit is 3,600 coulombs.

If I is the number of amperes of current strength, t the number of seconds it lasts, and Q the number of coulombs of electricity thereby conveyed, the relation between them is expressed by the formula:

$$Q = I \times t$$

Example—If a current of 80 amperes flows for 15 minutes the total quantity of electricity conveyed will be $80 \times 15 \times 60 = 72{,}000$ coulombs. This is equal to 20 ampere hours.

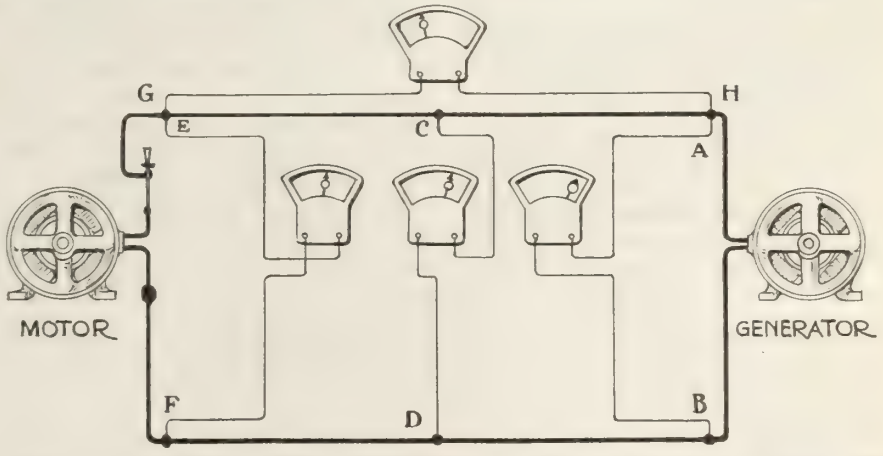

FIG. 4. AN ELECTRIC CIRCUIT ARRANGED IN A SIMILAR MANNER TO FIG. 2. THE SWITCH BEING CLOSED, PRESSURE DIFFERENCES CORRESPOND TO THOSE SHOWN IN FIG. 2.

The coulomb, representing as it does a definite quantity of electrical energy, can be defined with respect to the amount of work done by it, and it has been found that when one coulomb is

passed into a silver plating solution .001118 grams. of silver are deposited.

Resistance

The resistance of an electric circuit to the flow of current through it is readily understood by reference to the accompanying illustrations and by means of the analogy already established. As has been noted above, when no water flows through a system of piping the pressures existing between different points as A to B, B to C, and C to D, Fig. 1, are all the same and no pressure difference exists between G and H; but when water flows through the system, the pressure differences change in comparative magnitude, as was explained under pressure and voltage.

In a water or hydraulic system it may readily be surmised that these differences in pressure have something to do with the friction loss caused by the piping.

In a similar manner there exists a property of the electric circuit which affects the voltage. In Fig. 3 we note that the voltmeters across the two lines all register the same, while the voltmeter across the ends of the top conductor registers zero. When the switch is closed, as in Fig. 4, the relations of all these voltmeter readings change in a similar manner to those of the gauges of the hydraulic system.

From this similarity it may be argued that there is some property of the electric circuit which tends to impede the flow of current through it. This property is called the resistance of the circuit, and is measured in a unit called the ohm. This resistance increases as the length of the circuit, decreases as the area of the conductor is made greater, and varies with the different materials of which the conductor is composed.

Those materials which offer a relatively low resistance, such as the metals, are said to be conductors; while those which offer a relatively high resistance, such as glass, rubber, dry paper, etc., are called insulators.

Answers to Last Month's Problems

A. Magnetic circuit, armature conductors, and collecting devices or commutator and brushes.

B. Field magnets, with their exciting coils and pole pieces and the armature core.

C. Hard copper segments, mica insulation and steel frame or shell.

D. Carbon, leaf copper and copper gauze formed into suitable shapes.

* * *

This Month's Problems

A. Can electrical pressure exist without the flow of current or energy?

B. To what property do we give the names, voltage, potential and electromotive force?

C. What name is given to the unit of potential?

D. What name is given to that property of the electric circuit which corresponds to the rate of flow in hydraulics?

E. What measure of quantity of electric energy corresponds to the units used in everyday life, such as gallons, pounds, etc.?

F. If a motor runs for 2 hours and takes a current of 50 amperes, how many coulombs of electricity will have passed through the motor?

G. What is the unit in which resistance is measured?

SEARCHING FOR BURIED SHELLS

AS an example of the uses to which abstract science may be put the application of the induction balance to the finding of unexploded shells on the battlefields of Europe is of more than passing interest.

In the early days of the Hughes' induction balance the hope was expressed that the balance would aid in the prospecting for certain magnetic ores and would also aid the surgeon in the probing for iron and steel objects embedded in the flesh.

The Génie Civil of November 10 gives a description of a portable induction balance used for spotting live shells.

The problem was simply to devise a suitable portable instrument which would function properly, and at the same time would be easily carried.

The instrument consists of a pair of primary and secondary coils, so combined with a telephone and a "hummer" or vibrator that, when the one primary comes near a mass of iron, a sound is heard in the telephone, whilst the telephone will remain silent when the two primary circuits are exactly in the same condition. As the symmetry will rarely be perfect, a regulator is added to the instrument by means of which balance is established each time before use. The two pairs of coils are wound on two wooden discs, C and C^1, 60 cm. in diameter; the I and I^1 are the two primaries which, in the application of the instrument, are lying flat on the ground, and S and S^1 are the two secondaries; the distance between the centres of the two discs is 1.5 m., about 5 ft. The jointed arms with which the coils are connected in the way the diagram shows are made of wood; at the apex is the wooden handle, of which the observer takes hold; the main weight of the instrument is, however, taken up by a strap which is carried over the shoulder. The regulating device mentioned is mounted at the apex. It consists of two small concentric coils; the outer one is inserted in the primary circuit; the inner coil, in the secondary circuit, can be turned, and the angle between the two coils can thus be varied between 0 deg. and 90 deg. The vibrator and the induction coil and battery of three cells which actuate the vibrator are placed in a box which is carried by the observer's assistant; a flexible conductor joints the two parts of the instrument. The weight of the instrument is not mentioned. In conducting his search the observer, followed by his assistant, walks over the ground, keeping the flat coils as near the ground as is advisable and listens in the telephone, having previously tuned the regulator to silence. It is stated that a shell of about 10 kg. weight is easily discovered by this test if buried to a depth of 40 cm. or 50 cm.; a hand bomb would betray itself if buried to a depth of 30 cm. The maximum depth stated is only 20 in., which is not much. Fortunately the plow and spade of the farmer rarely approach this depth, and as live shells are dangerous objects this device should prove very useful.

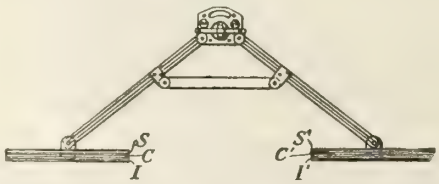

DIAGRAM OF INDUCTION BALANCE USED FOR SHELL FINDING.

It is said that experiments are proceeding for enlarging the range of the instrument, and improvements may be expected. It must be borne in mind, however, that the balance is a differential instrument, and that with greater depths and greater masses of iron, the differential effect on the two coils would be diminished; the coils and their distance apart would thus have to be enlarged, and the portability of the instrument would suffer. On the other hand, live shells are dangerous objects, especially to the farmer. Fortunately, his plough and spade do not, as a rule, go deep down into the earth.

URGE DEVELOPMENT OF HOME FUELS

FOR the purpose of studying Canada's fuel situation from every angle, an important body of civil engineers drawn from all parts of the Dominion met in session in the Physics Building of the University of Toronto, on March 26 and 27. The Canadian Society of Civil Engineers devoted two days of the convention to an exchange of views upon means of making Canada independent of the United States in regard to fuel. The first day's programme took account of the necessity for extra immediate production and systematic conservation of coal in order to tide the country over the next year or two of war scarcity, but it covered more particularly the problem in its larger sense. Full emphasis was placed in the various addresses upon the imperative need of developing Canada's fuel resources so that in the future when the supply in the United States falls short, the industrial life of the Dominion will not suffer. Increased production of bituminous coal in the Western and Maritime provinces and of peat fuel in Ontario, together with radical economies in the use of coal, were proposed.

AN air compressor cylinder unlike a steam cylinder requires only a small quantity of oil, a drop once in four or five minutes should be sufficient. The use of too much oil should be avoided as it causes an accumulation of carbon that may choke the valves and passages.

ELECTRICAL PORCELAIN

THE problem of securing desirable electrical and mechanical properties in the manufacture of porcelain used in the electrical industries is one beset with many difficulties and, while the products of some companies stand very high tests and seem in every way ideal insulators, the products of some other companies are well-nigh worthless.

Those who know the cause for this variation in quality do not seem to be inclined to distribute the information, but in general a porcelain mass will be the more resistant, the higher the proportion of kaolin and felspar also the finer the grain of kaolin used the higher will be the maturing point of the porcelain produced.

Composition

According to a paper by Arthur S. Watts appearing in the transactions of the American Ceramic Society the leading materials used in porcelain manufacturing are certain kinds of kaolin, which are very slightly plastic, quartz and felspar. Ordinary felspar displays basic properties in the fire, uniting with the silica to form silicates. Therefore the kaolin content must be in a definite ratio to the quartz and felspar for the production of desired insulating qualities.

Too much quartz makes the body too little plastic, thus making it difficult to work, and after burning the ware shows impressions and some warping due to the tendency of the clay substance to contract. Too high a content of felspar makes the body soft and liquid and increases the tendency to crack. A body low in felspar does not produce sufficient vitrification and hence decreases its insulating efficiency.

A porcelain body may shrink 15 to 18 per cent. and it is very important that the exact degree of shrinkage be known. No crazing or shivering is allowable in the glaze used on ware for electrical materials. If the glaze is too infusible the ware is likely to be dull, and if too fusible it is likely to be covered with blisters. Investigation has proven the condemnation of glazes containing metallic oxides to be unfair. Metallic oxides when used in glazes combine with silica forming silicates.

The plain bell used for low potentials and which is also practical and satisfactory for alternating currents up to 1,000 volts, does not meet the requirements of modern high voltage transmission lines. Up to tensions of 3,000 volts the ordinary double bell 75 mm. wide and 100 mm. high suffices, but above this voltage the question of further improvement arises.

At first insulators were glazed and burned, resting on the bottom edge of the bell, but the roughness of this edge seemed to cause the collection of drops of water and to prevent this, the insulator is now glazed all over, the glaze removed from the head and the insulator burned; the insulator is by this means made much more resistant and need not be so thick. The weight of porcelain used in the insulator is not of the greatest importance, but rather the quality of the porcelain and the kind of glaze.

Manufacturing Methods

In Europe, insulators are made by all five of the clay working processes, viz., turning, pressing, jollying, casting and dry pressing. The writer stated that he was familiar with all these processes except casting, but was not prepared to pass judgment on the superiority of any given process of working, as of course the product and its shape and size would greatly influence the method chosen. Dr. Seger, in his work, shows very conclusively that a semi-dry process in which the material to be pressed contains the highest percentage of water permissible for good pressing, gives the densest and strongest bodies. The turning of large insulators is done similarly to all clay turning, the product being made mouth up and the top finished when the ware is sufficiently dry to permit of its being inverted. For making threads, threaded tube like steel tops, or automatic boring apparatus is used.

Pressing is done in moulds. Clay is placed in the mould in a lump and by means of a plunger its exterior is forced to assume the shape of the inside of the mould while the plunger shapes the interior.

Dry pressing produces more exact shapes than any other method. The moulds used are of steel and are very expensive. The body must be in such shape that it will not stick to the mould. To obtain it in this condition some factories use the following process.

The clay, after drying and being thoroughly pulverized, is placed in wet cement or plaster boxes and allowed to absorb 10 per cent. to 20 per cent. moisture. The mass is then sieved thoroughly. Ten kilograms of the body will contain about 1 to 2 litres of water. Of course this proportion must be maintained exactly in order to insure a uniform shrinkage.

The moulds are sometimes complicated and are often composed of insertions. Ware is threaded by means of a screw inserted in the bottom before the clay is introduced and which is screwed out rapidly by means of a crank. The tendency is to make insulators without threads as these have always been a great source of trouble and loss in manufacture.

Porcelain which is not perfectly vitrified does not possess any great insulating efficiency even when perfectly dry.

Essential Properties

Essential properties of an insulator are: That it possess first of all a high efficiency as a nonconductor, that it stand without snapping any reasonable strain put upon it and that it withstand blows of missiles, etc., without breaking. Electrical, abrasion and tensile tests are made to show these properties in porcelain tested.

From a study of the electrical resistance tests it has been found that every specimen standing a superior test has a high silica and moderately low alumina content.

In series showing the effect of alumina content no great difference is shown in ability of specimens to resist abrasion. Much the same statement would apply to series showing results of varying of silica, medium high silica specimens seem to chip worse than extremely high silica specimens, while the low silica specimens show a lack of ability to resist abrasion.

The conclusion reached is that a moderately high silica and alumina content will bring a good strong porcelain but that not over 1 per cent. alumina and 6 per cent. silica should be used.

Shrinkage tests showed that there are three factors that may cause a variation. (1) The amount of clay substance introduced; (2) the variation in the kind of flux used; (3) the amount of silica present. Hence shrinkage may be varied to suit almost any case.

In closing it may be said that an ideal porcelain for electrical purposes may mature at any point between cone 6 or cone 12.

The bodies of high resistance porcelain in use in the United States employ potash almost exclusively as a flux, although some few may contain a small quantity of lime. The formation of small cavities in the porcelain weakens it remarkably in resisting strains. Porcelain must be thoroughly vitrified so that moisture cannot penetrate it.

FULL WAVE MAGNETIC RECTIFIER

By J. N. S.

THE accompanying illustration shows a full wave magnetic rectifier for charging storage batteries.

A battery, if not kept fully charged, loses part of its capacity for renewal, due to the hardening of the plates, and no treatment can bring it back to its first satisfactory condition.

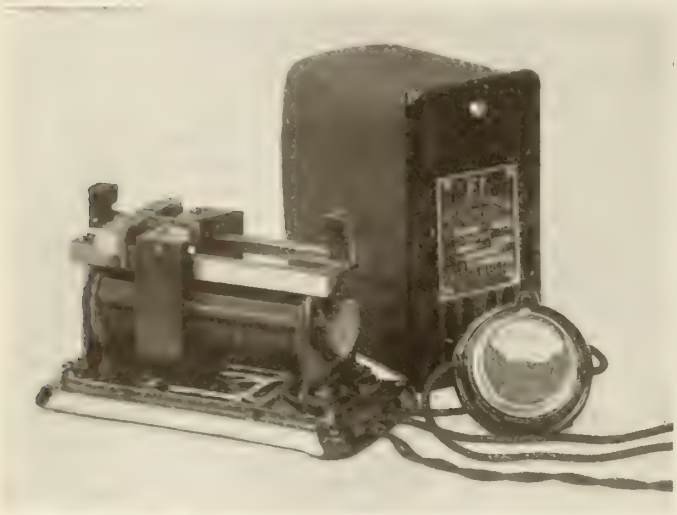
It is well known that most light and power current is alternating, that is, to reverse direction about sixty times a second and cannot be used to charge batteries. It is the purpose of the rectifier to change alternating current to direct charging current as it flows into the battery.

As to its operation, it may be said that the line voltage is reduced to the proper charging voltage by a special transformer and both the positive and negative halves of the alternating current wave are rectified into a steady unidirectional charging current which makes the cost of charging so low that the rectifier quickly pays for itself.

This device saves time, money and trouble, and it makes every lamp socket a charging station. It takes only a minute to screw the plug on the end of wire into a lamp socket and connect the other two wires to the battery, and the battery will be charged in a few hours without removal from the car, and at no more expense than for burning a 100 watt lamp for the same length of time. A complete charge for the average starting and lighting battery costs about six cents, which is at the rate of half a cent an hour to operate.

It is stated that the rectifier charges the battery in the most efficient manner. The charge starts at a high rate, from 10 to 15 amperes, which brings the temperature of the battery up to normal

working condition. This reduces the time required for charging, and as the charge nears completion the rate gradually reduces itself, due to the rising battery voltage, resulting in what is known as the "tapered charge." This tapered charge is impossible with any charging means which operates at a fixed low rate, but is automatically taken care of by the rectifier.



MAGNETIC WAVE RECTIFIER FOR CHARGING STORAGE BATTERIES FROM ALTERNATING CURRENT CIRCUITS

It is of interest to note that the rectifier is self-starting and not affected by line failures—if current is turned off, battery cannot discharge through the rectifier—and when current is turned on the rectifier starts itself, thus night charging is safe and saves time. An alternating current service requires the magnetic rectifier. Various types are portable and of 60 watt capacity, operating from lamp socket on 100 to 130 volt, 60 cycle alternating current. One form of this device will charge a 6-volt battery or two or more 6-volt batteries connected in multiple at an average rate of 10 to 15 amperes. It will fully charge the average starting and lighting battery over night. It measures 5 by 7 by 9 inches and has a weight of 14 pounds.

HIGH POWER SINGLE-RUNNER FRANCIS TURBINE

By F. R. A.

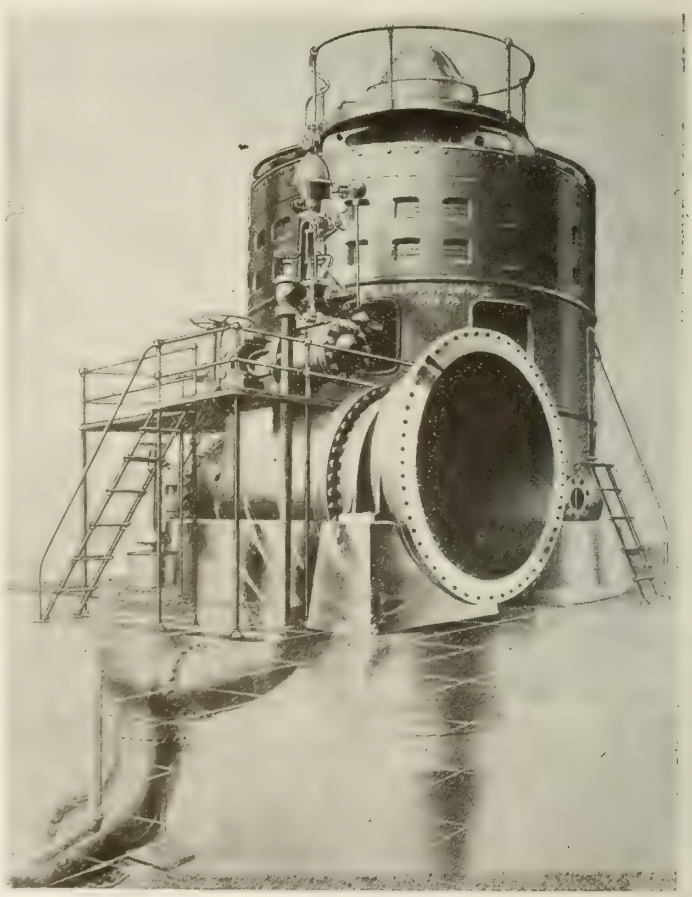
THE accompanying illustration shows a 12,000 h.p. single-runner, Francis turbine recently installed in the Roosevelt plant of the United States Reclamation Service as developed at the S. Morgan Smith works at York, Pa.

It may be stated that the installation of first machinery in the "Roosevelt" power station dates back a decade ago, at which time the original turbine unit was built. There have been installed three duplicate units of the first type used, each consisting of a 30½ in. wheel, having a maximum capacity of about 1,250 horse power, under 220 feet head. The plant was laid out for a total development consisting of six units, all of which are now supplied from the same pipe line and all of which are vertical shaft turbines, directly connected to vertical shaft generators.

It is of interest to note that the No. 4 unit is of a little larger capacity than the No. 3, consisting of a 36½ in. wheel, while the No. 5 unit is an exciter unit, driven by a 17 in. turbine. Each of these units is mounted in a spiral, cast iron pressure case, on top of which is mounted the generator. The No. 6 unit, however, is of much greater capacity than any of the others and consists of a vertical shaft, scroll case, Francis type unit, consisting of a 53 in. wicker gate turbine, as shown in the accompanying photograph.

This single-runner hydraulic turbine has a maximum capacity of 11,500 h.p. under the maximum head of 220 feet. This turbine operates at a constant speed of 300 R. M. P., over a range of head varying from 90 feet minimum to 220 feet maximum. This identical wheel was tested in the Holyoke testing flume, and computations made from the Holyoke results showed the wheel to be capable of operating at efficiencies ranging between 84 per cent. and 89 per cent. over this entire range of head. This No. 6 unit was installed and was afterwards tested by government engineers, who obtained results showing even greater efficiency than that obtained at Holyoke, which results are undoubtedly correct, as the operating conditions in connection with the scroll case give the turbine the advantage of the very best conditions of application of the water to the runner at a constant velocity.

It is claimed that the most remarkable part of this entire installation of turbines at the Roosevelt plant is the great range of head over which they are capable of maintaining a constant speed at good efficiency. The unit shown in the illustration is direct connected to a General Electric alternator with direct connected exciter and thrust bearing for supporting the weight of all the rotating parts. The regulation of this unit is effected by means of an oil pressure governor of the Woodward type, designed specially for use in connection with vertical shaft, Hydro-Electric units.



FRANCIS VERTICAL WATER TURBINE WITH SUPERIMPOSED ALTERNATER.

THOUGH the effect of clearance and of heating the air before compressing can be calculated by formulae it is well to bear in mind that the results so found are not always in agreement with actual operating conditions. The leakage of air past valves and piston, the choking of air passages, and bad valve action are variables that cannot be determined by formulae. Volumetric efficiency is most accurately determined by measuring the air delivered and comparing it with the displacement of the compressor; such a method includes all factors affecting the performance of the IF a compressor has poorly designed intake passages, the air as it enters the cylinder may be at a temperature several degrees above that of the atmosphere. The metal of the cylinder becomes quite hot after the compressor has been running for an hour or more, and after travelling through long and intricate passages the air may be heated to 100° or over.

Notes on the Design and Testing of Air Lift Pumps-II.

By A. W. Purchas *

The air-lift pump has become one of the most economical methods of raising water, the simplicity of construction and the almost entire absence of moving parts giving reliability in operation and avoiding the necessity for skilled supervision. The design of these pumps being subject to more or less development the subject matter of the following article is of more than passing interest.

Operation of the Pump as a Whole

There are several different methods of approaching this question, one of which was enunciated by Dr. H. Lorens. This takes account of friction and slip, but starts off with a "constant" which the tests by Messrs. Davis and Weidner showed to be as variable as any quantity can be. This theory is not reproduced here as it is cumbersome, and does not bring out the features of operation of the pump.

Another method of approaching the subject brings out better than either of the foregoing the details of operation of the process, and may be called the Displacement Theory. Fig. 7 represents the pump prior to the injection of any air. Since the base of the eduction-pipe is open, the pressures on both sides of the horizontal plane X—X are equal, and the liquid stands at the same height inside the pipe as outside.

Fig. 8 represents the conditions after a single bubble of air has been injected. The weight of this bubble of air is negligible when compared with an equal volume of liquid, and the bottom of the eduction-pipe being open the pressure on the two sides of the plane X—X will remain balanced; therefore there must remain in the eduction-pipe after the injection of the air the same volume of liquid as before. The liquid displaced by the air must therefore move upwards, raising the surface of the liquid inside the eduction-pipe above that outside.

Let H be the amount of the rise.

V be the volume of the air bubble, and A be the cross-sectional area of the eduction-pipe. Then

$$H = \frac{V}{A}$$

The injection of the volume V of air has done work equal to ½VH due to displacement alone, but the bubble will rise through the column of liquid, expanding as it does so and thereby increasing H. Neglecting friction, none of the energy originally contained in the air-bubble is lost until the bubble breaks the surface of the liquid and escapes into the atmosphere. When the air has finally escaped, then it may be said that the energy has been wasted in slip; but not before.

Supposing the air to be injected into the eduction-pipe at such rate that before the first bubble escapes to the atmosphere the total volume accumulated in the eduction-pipe, say V^t is such that the head $\frac{V^t}{A}$ is greater than the lift L.

Then the pump will discharge a volume of liquid equal to A (H—L). This is the volume that is violently discharged when an air-lift pump is started up. The loss of this volume from the eduction-pipe produces an unbalanced head, equal to H—L, on the plane X—X, which will force more water into the base of the pump. From this point onwards the operation of the pump may be regarded as a head H—L forcing liquid into that area of the eduction-pipe, which is not already filled with air. Analysis of the published results of tests seems to show that the great loss in the pump is not by slip, but of this head H—L due to entry losses.

Tests yielding high efficiency always show either one or both of the following features: low velocity of the rising mixture through the foot-piece, or else a low ratio by volume of air to liquid at this point which is the result of great submersion. The effects of great relative submersion may, however, be offset in many existing wells by the relative high velocities of the mixture leaving the eduction-pipe with consequent high friction losses. All of which suggests that the eduction-pipe should be of as great cross-sectional area as the well permits from its base to at least the level from which the liquid is being raised. The loss by slip of this length is negligible, as we have seen, and the larger the pipe the less will be the loss of the head H—L. Above this point, however, the velocity of the rising mixture must lie between certain definite limits, otherwise the loss by slip will be excessive; therefore the area of the eduction-pipe must bear a definite ratio to the volume of mixture flowing through it. What this ratio should be cannot definitely be stated on the data at present available, but it is hoped that the ideas here put forward may lead to more thorough tests being made of pumps in the future, and the publication of the results.

If the velocity with which the air-bubbles will rise through the liquid can be calculated, then the total volume of air in the eduction-pipe at any instant of time can be found from the known rate of ejection. If this volume produces a head less than the lift, then with the submergence fixed, a greater rate of air-supply must be used for the pump to deliver any liquid. If the rate of air-supply is fixed, then a greater submergence must be provided, in which sufficient air can accumulate to produce the necessary head. A definite volume of air must be accumulated below the water surface inside the eduction-pipe for the pump to work at all.

At the other extreme it is conceivable that the air could be injected at such high rate as to entirely hold back all liquid from entering the base of the eduction-pipe, once the original contents were discharged. Such a state could hardly be obtained in any pump installation, but probably could be brought about with a 2-inch eduction-pipe, 12-inch air-pipe, and high rate of air supply. Experiments bear out these statements, for a series of tests on a pump at increasing rates of air supply show that below a certain rate there is no discharge. Above this point the discharge of liquid increases with the rate of air supply, and then begins to grow less as the rate of air supply is still further increased, Figs. 9, 10, 11.

This Displacement Theory also shows that the volume of air required to raise a given quantity of liquid is independent of the density of the liquid, if we neglect losses from friction and slip. However, the pressure equivalent to the required submersion, and therefore the energy contained in the air injected, varies as the density of the liquid.

Submersion of the Air Injection Foot-Piece

There is no rational formula known that will determine the most efficient value for the submersion, and only a few published tests touch on the point. Messrs. Davis and Weidner made many small scale laboratory tests which are very inconclusive. Mr. Edmund Ivens also records some tests on a large scale in his book, "Pumping by Compresed Air."

The Displacement Theory, already outlined, shows that the submerged portion of the eduction-pipe is primarily necessary as an accumulator for the air. As will be seen later (pages 25 and 26), there is no such thing as a definite volume of air required to raise a given quantity of liquid to a given height, as the volume of air varies according to the submersion adopted. This conception of an accumulator for the air suggests that greater proportionate submersion is required for low lifts than for high, and that rather than bear a fixed ratio to the lift, the most efficient value will bear a definite relation to the rate of air supply and cross-sectional area of the eduction-pipe.

Current practice favors greater ra-

*Read before the Institute of Electrical Engineers. November, 1917.

tios of submergence to lift the lower the lift, and the following values are a fair average:

Lift	Submersion Ratio—Submersion / Lift	Submersion
25 feet	4.00	100
50 feet	3.00	150
75 feet	2.33	175
100 feet	2.00	200
150 feet	1.70	255
200 feet	1.38	275
250 feet	1.22	305
300 feet	1.00	300

Messrs. Davis and Weidner report as the result of 108 tests on a lift of five feet with submergence varied from 30 to 88 per cent.: "The efficiency increases as the percentage of submergence increases for all rates of input, and all practical percentages of submersion." It seems quite possible that a rational formula for determining the most efficient submergence may in time be developed from the Displacement Theory.

A Method of Designing Air-Lift Pumps

To the designer who lacks the data which the larger manufacturers have accumulated, the following method is suggested:

Let L be the lift in feet.

S be the submersion in feet.

V^w be the volume of water to be pumped per minute in cubic feet.

V^a be the volume of air required per minute measured at atmospheric pressure and a temperature equal to that of the water to be pumped.

P^a be the absolute pressure per square inch of the atmosphere.

P^s be the absolute pressure per square inch of the air under the submersion head S.

Then the energy supplied by the air to the water is:

$$144\ P^a\ V^a \log^e \frac{P^s}{P^a} \text{ — foot-pounds,}$$

and the work done on the water is 62.5 V^wL foot-pounds.

Then, if the efficiency of the pump were 100 per cent., these two quantities would be equal. In order to apply this method, two assumptions must now be made, namely, the submersion and the efficiency of the pump.

Submersion.—A guide to the probable best value for this has been given already, and these values may be taken, though it will be seen later that they may need modification as the design proceeds.

Accepting these values, then—

$$P^s = P^a + 0.434\ S.$$

Efficiency of the Pump.—This at first seems a very rash assumption, but it is the author's belief that a careful study of this and other papers will show that it is not so. The following test figures stand out as the best so far reported, and analysis of other published tests shows no reason why they cannot always be duplicated:

(1) With the reverse process of compressing air by entanglement with falling water, an efficiency of 81 per cent. has been obtained in Germany, and 71 per cent. at the plant of the Dominion Cotton Mills Co. at Magog, P.Q., Canada. This latter plant was the first installation designed on this principle.

(2) Series D of tests at Oilfields show that an efficiency of 72 per cent. can be obtained with an air-lift pump on lifts of 300 feet, and an analysis of other published tests suggests that in each case higher efficiencies could have been obtained at other rates of working, or by modification of the designs along the lines already outlined. Furthermore, most writers on the subject have in the past conceded that higher efficiencies are obtainable on low lifts than on high lifts.

There is good ground, therefore, for assuming an efficiency of 70 per cent. for all lifts up to 300 feet. This may not be obtained with the first eduction-pipe installed, but in the majority of cases the first eduction-pipe is not the final one, but is installed to find the service pumping level and the capacity of the well. A series of tests made on the first pipe at varying rates of pumping should enable the above efficiency to be obtained with the final one.

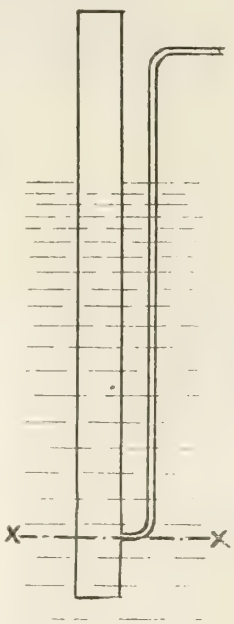


FIG. 7

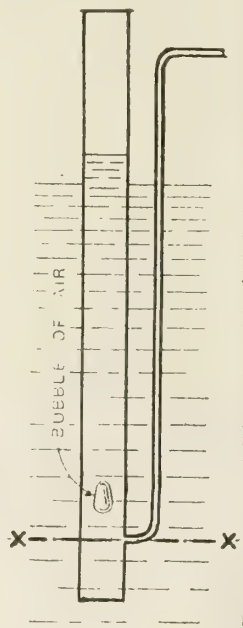

FIG. 8

These two assumptions being made, the volume of air and its initial pressure can be found from the formula:

$$0.7 \times 144\ P^a\ V^a \log^e \frac{P^s}{P^a} = 62.5\ V^w L.$$

It must be borne in mind that the above volume of air is not the same as the displacement of the compressor-piston. It is usually wise to have a reserve capacity in the compressor to cover such factors as encrusted eduction-pipe, a demand for greater output of water, and wear of the compressor itself. The manufacturers should therefore be given the fullest details, since the power required to deliver any volume of air varies very widely with the speed of the compressor, and the ratio of the desired output to the full capacity of the machine. It may be noted here that high volumetric efficiency alone is not the desirable feature of a compressor, nor high mechanical efficiency alone, but the highest combination of the two. The best machine is that which will deliver the required volume of air at the given pressure with the least expenditure of energy in the prime mover. Some of the latest designs of air-valves obtainable do not promise high volumetric efficiencies, but they conduce to high over-all efficiency.

Reference to the tests in the tables will show that 40 per cent. of the energy generated by the prime mover may be wasted in the compressor itself, and therefore that as much attention should be paid to the choice of the air-compressor as to the design of the eduction-pipe and foot-piece.

Having finally determined the best value for the air-pressure, submersion and volume of air required, the air piping, foot-piece and eduction-pipe can be designed. In proportioning the air-pipe, allowance should be made for the temperature of the air leaving the compressor being high, and the volume therefore greater than would otherwise be the case. After making this allowance, the velocity of the air in the pipes should not be over 20 feet per second. The design of a foot-piece has already been discussed, and will not be repeated here, neither the design of an eduction-pipe along the lines suggested by the Displacement Theory. But to enable others to reproduce the design, of which series D of tests in the tables show the capabilities, the original calculations for this pump are here given:

Assumptions and Conditions Based on Previous Tests of the Same Well

Volume water to be raised per second, 0.50 cb. ft.
Volume of air measured at atmospheric pressure and 70° F. required per sec. 3.30 cb. ft.
Lift ..... 300 ft.
Total length of eduction pipe..... 625 ft.
Velocity of rising mixture to be maintained, between .....8 and 15 ft. per sec.
Air pipe to be kept outside eduction pipe.

Available pipe of suitable dimensions:

Nominal Size	Actual I.D. inches	Cross-Sect. Area sq. ft.
4-inch line pipe	4	0.087
5 3/16-inch casing	5	0.136
6¾-inch casing	6¼	0.210

Calculations

Pressure of air on leaving foot-piece —141 lb. gauge—3.30 cub. ft. of air at atmospheric pressure, and 70° F., will be 0.308 cub. ft. at 141 lb. per sq. in. gauge pressure, and 70° F.

The increase in volume of the air is 3.30-0.308 cub. ft. in a length of 625 ft. of eduction pipe, equivalent to 0.0048 cub. ft. per foot-length of pipe.

For a velocity of 15 ft. per second in 4-inch pipe, the volume flowing must be 1.305 cub. ft., which in this particular case will consist of 0.5 cub. ft. of water and 0.305 cub. ft. of air. If L be the feet of 4-inch pipe required between the foot-piece and its junction with the next larger size, then:

$$0.805 = 0.308 + 0.0048\ L,$$

whence $L = 103$ feet.

In the next proposed size—5 3-16-inch casing—a velocity of 15 feet per second will require a volume of 2.10 cub. ft., which will be composed of 0.5 cub. ft.

of water, and 1.60 cub. ft. of air. Calling the required length of 4-inch and 5 3-16 inch pipe combined L_1, then:

$$1.60 = 0.308 + 0.0048\ L_1,$$

whence $L_1 = 270$ feet,

and the length of 5 3-16-inch required is 167 feet.

	ft. per sec.
At foot-piece	9.3
At top of 4-inch pipe	15.0
At bottom of 5 3/16-inch pipe	9.3
At top of 5 3/16-inch pipe	15.0
At bottom of 6⅝-inch pipe	10.0
At top of 6⅝-inch pipe	18.0

Among the more important conclusions to be drawn, which have not been previously emphasized, are the following:

(1) The apparent lack of agreement of different tests with any definite laws is due to two main causes: one, that the volume of air stated to have been used is too often the displacement of compressor-piston, or too high a percentage of this, which introduces an error of 10 to 60 per cent.; the other is the lack of segregation of the losses. For scientific purposes it is obviously useless to lump together the losses in the compression process and those in the eduction-pipe. The former are fairly well understood, but the latter are quite unknown, and will remain so, as long as only tests of the over-all efficiency of installations are made. If the laws governing the losses in the pump proper are to be studied, then a test must give the energy contained in the air immediately after passing through the injection foot-piece.

(2) That the greatest loss in an air-lift pumping installation is in the air-compressor, and therefore that the best compressor is none too good for a permanent installation.

(3) That the next greatest loss is the loss of head at entry.

(4) That any formula for calculating the submersion required would be better stated in the terms of "the volume of air used per second, at a pressure equivalent to the head of submersion," rather than in terms of the lift. This is suggested by the displacement theory conception of the submerged portion of the eduction-pipe as a space for the air to accumulate and raise the water by displacement.

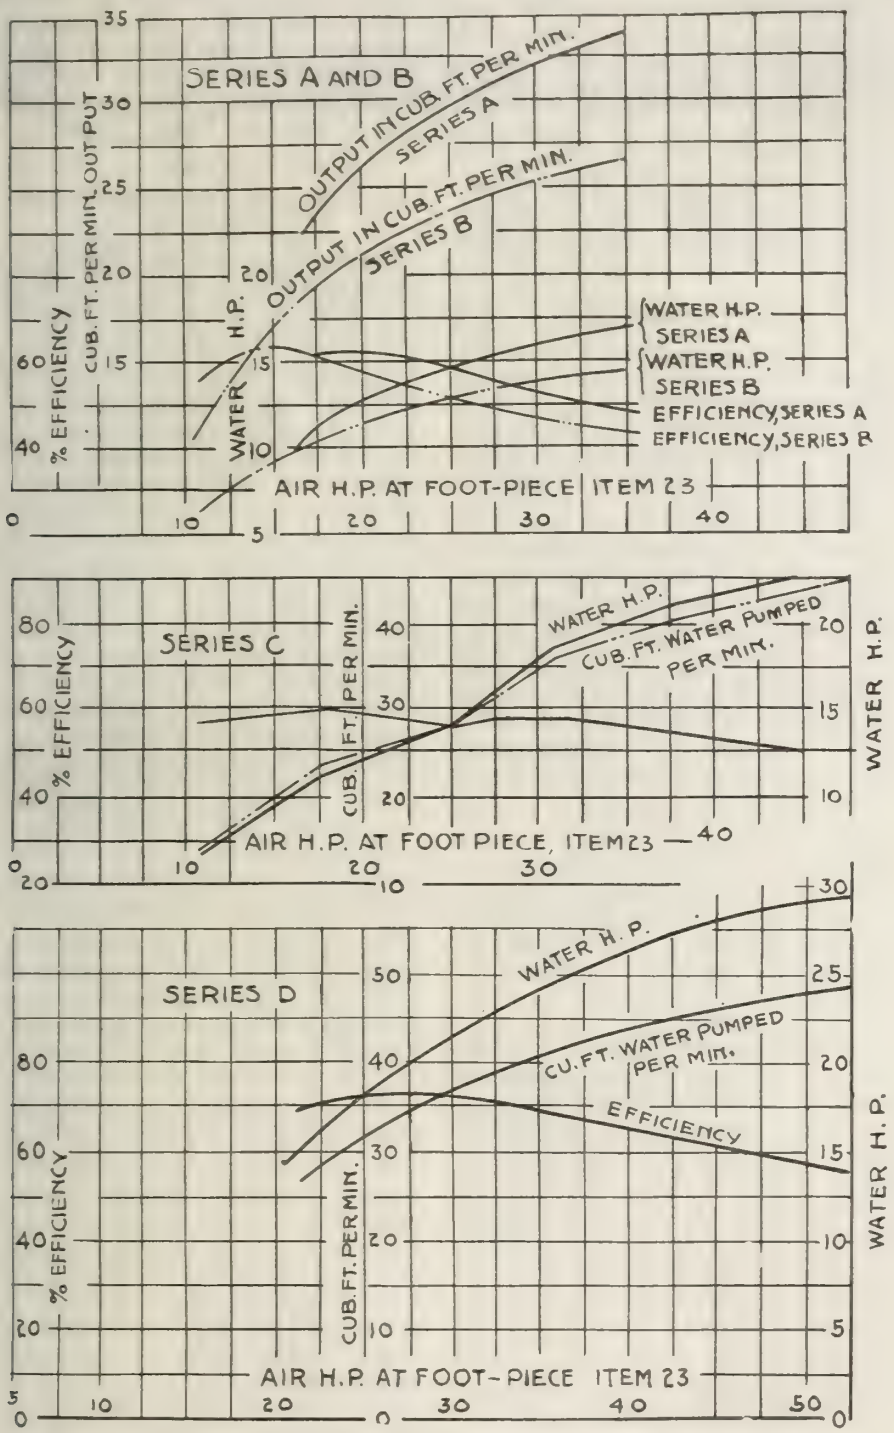
(5) That every ounce of compression which the air is compressed above that pressure, which is equivalent to the submersion head, is so much energy wasted, and that attention should be paid to the design of the foot-piece and the air-pipe with the object of reducing those losses to a minimum.

(6) That a valuable item of information to include in the report of any test is the ratio of the volume of air to water at a point immediately above the foot-piece, and that the ratio by volume of air to water at the outlet of the pump is of little comparative value, since the volume of air is not a measure of the energy contained therein, unless the initial pressure is included in some form.

(7) That the hotter the liquid to be pumped, the higher will be the efficiency of the pump. It has been shown by Professor Randall that an efficiency of 100 per cent. is possible under certain conditions when pumping water at 200° F.

(8) That many flowing oil-wells are in reality "air-lift" pumps, using natural gas in place of air. Mr. A. T. Beazley, A.M.I.C.E., has obtained very encouraging success in making wells flow which had previously to be pumped, by applying to them the principles of the air-lift pump. The great obstacle to be overcome is the lack of control both of the quantity of gas and oil, and of the point of mingling of the two.

(9) That considering the different forms of steam-engine usually used in conjunction with different types of pumps, that the fuel consumption of an air-lift installation can be made to compare very favorably with that of any other type for raising liquid more than 75 feet from a well. For shallow wells centrifugal pumps will probably prove more economical.



FIGS. 9, 10, AND 11, SERIES A. B. C AND D. WATER PUMPED, ETC.

Hence pipe desired is composed of: :

105 feet of 4-inch line pipe.
167 feet of 5 3/16-inch casing, and
355 feet of 6⅝-inch casing—a total length of 625 feet.

[Note.—6⅝-inch casing is the largest size pipe available which can be inserted alongside the air-pipe in the well.]

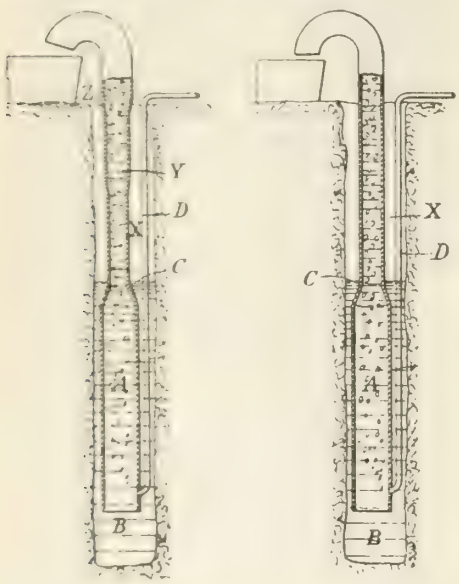
Using the above lengths of pipe, the average velocity of the rising mixture will be:

AIR LIFT PUMPS

A PATENT recently granted to A. W. Purchas of Wolverhampton, Eng., relates to an improvement in the design of air lift pumps whereby a much greater efficiency is claimed.

Experiments by the inventor are said to have proved that there is considerable loss due to friction, sudden changes in velocity and eddies in the submerged portion of eduction pipes of air lift pumps as at present constructed.

This is remedied as shown in Figs. 1 and 2. It is assumed that the eduction pipe A is immersed in a well B, in which the level of the water is at C before the air is forced into the pipe by the air pipe D. The cross section of the submerged portion of the eduction pipe is as large as possible, consistent with leaving of sufficient passageway between the pipe and the inner walls of the well casing to prevent undue frictional losses



rue to the velocity of the flow of water to the eduction pipe.

In the submerged portion of the pipe there will be no loss by slip. At a point near the level C the cross-sectional area s reduced as shown at X. To reduce the frictional losses of the rising mixture the pipe enlarges at Y and again at Z. Fig. 2 shows a modification in which the portion of the pipe above the water level C to the outlet has a constant area which is less than the submerged part.

WARMING BY HEATED AIR

By C. T.

WARMING by heated air should be divided into two methods or systems: one in which the air is warmed by passing over hot-water or steam-heated surfaces, the other in which fire-heated surfaces are used to afford the warmth. When the air receives warmth from hot-water or steam coil, or radiators, no effects prejudicial to the air or health are experienced, the general results are agreeable, and the cost in fuel low.

Whether the apparatus consists of a number of radiators, each in a case or chamber through which air is caused to pass, or whether one large battery of coils or of radiators in stacks has the air blown through it, the result is the same with the air entering the rooms, as it cannot be overheated, or over-dry or carry odors of scorched particles of dust (organic matter). In other words the air is warmed under much the same extent as with the exposed radiators, the only difference occurring when the hidden heating surfaces are not kept reasonably clean. The whole may be looked upon as a hot-water or steam-heating apparatus so far as temperature of the heating medium and cost of fuel is concerned, but the first cost of the installation is usually higher than a hot-water or steam apparatus having exposed radiation.

When the hot-air system has some form of stove as the medium by which the air is heated, it does not follow that the air is given disagreeable qualities, but it is easily possible to do this if the stove is not of a specially suitable kind. Up to a certain temperature a heated surface has no noticeable ill-effect on the air in contact with it, and if the surface is one that cannot be heated beyond the correct degree by careless stoking, for example, then it matters little whether it is a stove, or hot water, or steam that heats the air. A surface heated by fire heat direct and one heated by hot water have no different affect on the air if the temperature of each is alike at all times.

As a rule a hot air installation with a stove is less expensive to instal than one with hot water or steam for the heating medium, while the cost of fuel is very low in both cases. With large installations heated from a central chamber, each may require an air propeller to cause the air to pass along the ducts to the rooms, while with small installations the extracting action of chimneys in the rooms is relied on to induce the warmed air to flow in.

MACHINERY MARKET IN BRAZIL

AS to the requirements of Brazil generally these are exceedingly diverse. In one market alone—that of mining machinery—there are boundless opportunities for the British manufacturer. Mining is, however, but one phase, and one phase only, of the republic's industry. Agriculture, which forms so large a share of the people's occupations, demands increasing supplies of implements and machinery; the many large towns are purchasers of electric lighting machinery, pumping plants, steel rails for tramways and mines, iron and steel manufactures, motors and stationary engines, tubes, structural material, tools, cement, and sewing machines. Windmills, refrigerators, huge quantities of barbed and plain fencing wire, lubricating oils, and innumerable other articles of a similar nature are constantly in repuest.

Neither should the great sugar producing industry be overlooked, with its demands for the latest type of crushing plant and distilling apparatus, while a further opening in the engineering line is to be found in connection with the many irrigation plants and installations of pumping works that are being installed, in addition to the equipment of numerous plants, large and small, to make use of the hydro-electric power available.

The most important of all Brazil's manufacturing industries is, however, that of cotton textile. The principal cities and towns in which textile machinery is needed are those of Rio de Janeiro, Sao Paulo, Petripolis, Sorocaba, Maranhao, Pernambuco, and Bahia.

WATERPROOF WHITEWASH

By B. M.

A NEW mixture has been recently introduced producing a waterproof whitewash. The influence of bichromate of potash on glue, rendering it insoluble when once dry, is made use of as follows: Dissolve 1 pound of glue in 3½ pints of water. Dissolve 3 ounces of bichromate of potash in ½ pint of hot water, and mix the two solutions. Then add enough of whiting to produce the right consistency, and apply in the usual manner. The action of the sun on the potash and glue render them insoluble and waterproof. The mixture adheres firmly to slate, glass, metal, masonry and plaster. Authorities seem to vary on the subject of the amount of bichromate of potash required to make glue insoluble; one-fortieth by weight is considered by many to suffice, in which case one ounce would suffice for 2½ pounds of glue. Again, the weight of whiting that the above amount would hold together and bind to any surface should not be more than could be carried in 4 pints or 2 quarts of water. This is a matter that the experimenter must asecrtain for himself, on a small scale preferably.

Glue dissolved in skim milk becomes insoluble when dry and might serve the purpose, and 1½ pounds of the cheapest sweet oil added to 8½ pounds of quicklime while slaking makes a well known insoluble coating that is available everywhere in India. The pores of the most porous plaster are readily filled with good limewash, and, if it is waterproof, one coat well applied should protect the plaster against saturation. A thick porous wall takes a little longer to penetrate than a thin one, but it also takes so much longer to dry. An impervious outer coating renders them both equal.

The need for cheap waterproof coatings in India is brought to mind in each succeeding rainy season when the monsoon wind drives the water through our very porous walls. Although a damp atmosphere at a temperature of about 80 degrees has no bad effect on public health it is most injurious to household goods and to merchandise of many kinds, besides being destructive to buildings.

THE success of a lay-out of tools is dependent on the sound judgment of the designer, which in turn can only be based on past experience and familiarity with the best shop practice.—Herbert.

Steam and Its Generation

PIPE FITTING

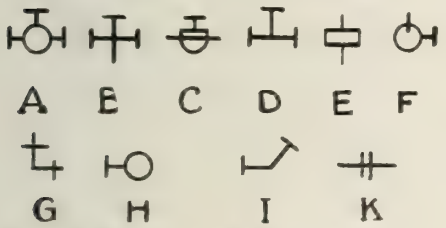
By M. H. Potter

Piping Laying Out

THE conventional signs for pipe fittings and pipe lines are shown in Figs. 1 and 2. Considerable time is saved, when a job of piping is to be done, by putting it upon paper. If the dimensions are laid down, each piece may be cut to the right length, and everything will go together without any further fitting and without spoiling pieces of pipe by cutting them too short. In laying out, always work from the centre of one fitting to the centre of the next, making the correct allowance for the fittings and then adding for the threads. Thus it is necessary to work to the actual dimensions of the fittings in order that the over-all dimensions of the pipe lengths may be obtained. If this rule is followed there will be no errors in purchasing and checking the pipe and fittings, and no trouble in putting them in place in accordance with the drawings.

Testing Pipe and Fittings

Although a piece of pipe is supposed to



A—Globe valve
B—Cross

FIG. 1. SOME SYMBOLS USED IN PIPING DIAGRAMS.

withstand a certain number of pounds pressure to the inch, there will always be found pieces of defective pipe and fittings. It is therefore necessary to test each pipe system as soon as it is in place. The testing may be accomplished by either steam, water or air. Water pressure is preferable if it can be easily obtained, the leaks show up readily and are therefore more easy to locate. Close inspection when the cutting and erecting is done prevents leaks which otherwise will develop under the test. In most communities the inspection law requires that a certain pressure be maintained for a given time. As steam condenses in pipes a leak can generally be detected from the dripping water, unless the leak is on the top side of a horizontal pipe. Should this be the case, mix a bucket of strong soap-suds using soap powder or soft soap. With a paint brush go over the weld of the pipe and the joints at the fittings. Wherever a leak blows bubbles through the soap-suds, mark with a piece of chalk.

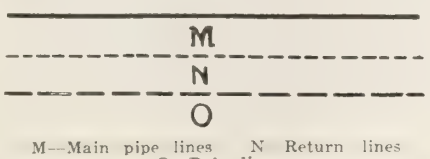
Draining Pipe Systems

Always drain the pipes in the direction of the flow of steam. Do not lead the condensation water back to the boiler by inclining the steam pipe in that direction. There is always danger of water in the bottom of the pipe being held up by steam flow with boilerward drainage; when a sudden demand comes for an increased flow of steam, the water all along the pipe is picked up by the steam rush and forced out of the pipe into the engine or other steam consuming device at the far end of the pipe line. Separators should always be used between engines and long pipe lines, avoid pockets and traps and there will be no trouble with rushes of water into the engine or other undesirable places for condensation water.

Dead Ends and Drips

No matter where placed, a dead-end always fills with water and should always be avoided if at all possible. In a large pipe if the dead end projects vertically upwards, the water may run out as fast as it collects, but unless it is drained in some way, it will surely fill with water. When a circulation has to be maintained in a dead end, a drip should be provided which will take care of the water of condensation as fast as it collects. If this is not done a loop must be made. Either hand or trap operated drips are used to prevent the loss of steam. When there are a number of drips, they may be made to work through a single trap by means of a receiver into which all the drips discharge, the trap taking care of the contents of the receiver.

It is necessary to place a check valve in each drip pipe in order that water may not be blown back into any pipe when that one is not in use and one or



M—Main pipe lines N Return lines
O—Drip lines

FIG. 2. CONVENTIONS USED FOR DISTINGUISHING VARIOUS PIPE LINES.

more of the others under pressure.

Condensation water may be returned to the boiler by the use of a steam loop. This is a dead end, so arranged that when full of water that the water will run out by gravity, leaving the dead end full of steam to repeat the operation. In Fig. 3, the steam loop is shown in connection wtih a steam boiler. A check valve A is placed in the pipe which enters the boiler at any convenient point. The system that is desired to be drained is connected with the pipe D; this acts as a dead end, the check valve closing the lower end of the pipe and against the entrance of steam from the boiler side. Any steam which may be present in pipe D is condensed and runs down upon the valve, filling the pipe to some point in the vicinity of B, or so high that the weight of water on the check valve A forces open that device, whereupon the water in pipe B flows by its own weight into the boiler.

Or a portion of the water flows in, until the weight of water in the pipe is unable to hold the check valve open.

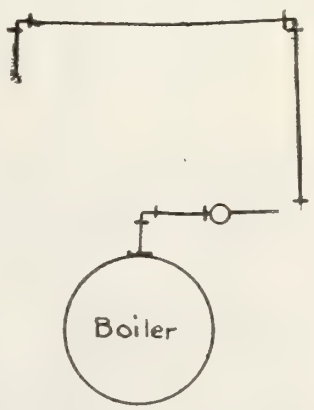


FIG. 3. DIAGRAM ILLUSTRATING THE PRINCIPLE OF THE STEAM LOOP.

Then the valve closes and remains closed until enough water to again open the valve collects in pipe B.

Making Up Flange Connections

Care should be taken to have all union surfaces clean and free from sand, metal chips or any other foreign matter, when making up flanged joints. A good gasket fit can only be secured in this manner. When tightening the bolts between a pair of flanges, make sure that the flanges are brought to an easy bearing, just touching the gasket, and then all the nuts are screwed down easily until they all bear evenly. Then screw up each nut about a quarter of a turn, passing from one to the other until all have had a quarter turn. Then go over them all again and again in the same way, until the joint is tight and the bolts all

have an equal strain upon them. Avoid screwing up one nut tight and leaving another one loose. When the flanges are the same distance apart all around the pipe, then it is certain that the bolts are all bearing evenly and the joint will not leak.

Steam Pipe Expansion

Expansion joints are sometimes used to take care of the elongation caused by the expansion of steam. It is, however, when possible, preferable to use one or two angles in the pipe and let the lever arms thus secured take up this elongation by swinging sidewise. Such a method of connecting two boilers is shown in Fig. 4. The correct arrangement is shown by the full lines and an incorrect one by the dotted lines.

Cutting Gaskets and Packing

By hammering the sheet of packing lightly over the edges of the flange, taking care not to hit with a corner of the hammer, or to strike hard enough to mar the edge of the iron surface, is the best way to cut gaskets, especially for irregular work, although soft gaskets may be cut to measure in advance by a washer cutter. Red lead is the best for a permanent joint but if it is

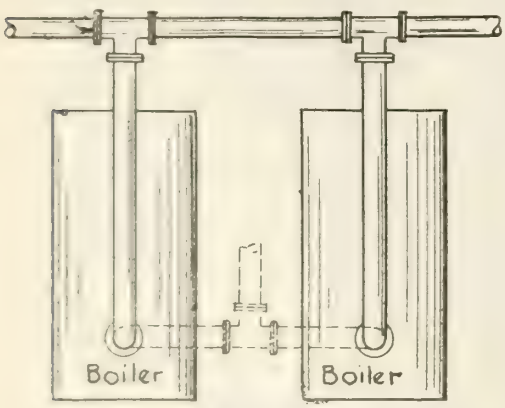

FIG. 4. PROPER METHOD OF CONNECTING BOILERS AND ALLOWING FOR EXPANSION.

desired to remove the gasket whole, cover it with plumbago before making up the joint.

Permanent screwed joints in pipe are made leak proof by the use of red lead. Screwed joints which have to be taken down frequently should be daubed with plumbago; spread it thickly upon threads.

Regrinding and Packing Valves

Soapstone with a little cylinder oil or plumbago should be used in the stem packing of steam valves. The stems of globe valves should be repacked with wicking and either plumbago or soapstone and cylinder oil. As soon as a leaky valve is discovered, remove the bonnet, true up the seat and disk. A good set of valve grinding tools as now on the market should be purchased and used immediately upon the discovery of a leaky valve.

The Proper Use of Pipe Fitting Tools

When cutting pipe with a hack-saw considerable care is necessary to prevent the pipe from ruining the saw. After the teeth cut through the wall of the pipe, while the saw is moving over the cut-through portion on one side of the cut, the saw is moving toward a sharp wedge-shaped section of pipe on the far side of the cut; and when the saw is drawn past this point if pressure is exerted the teeth against which the pipe bears will be split off the saw. It is necessary, therefore, to cut around the outside instead of cutting squarely through it.

A dull tool will not make a good pipe thread. Care should be taken to see that all dies are to size, as a first-class joint cannot be made when the thread screws in the fitting and shoulders. A Stilson wrench should be used rather than pipe tongs; however, chain tongs hold their grip equally as well on large pipe.

MODERN PRACTICE IN APPLYING GAS FIRING TO STEAM BOILERS*—III.

By T. M. Hunter, M.A., B.Sc.

The problem of finding the most satisfactory boiler for gas firing is to be solved by the boiler which abstracts the heat most successfully from the hot gases passing. There are several lines along which improvements can be made.

Possible Improvements

The first is to increase the surface exposed to the hot gases. The greatest resistance to heat transfer is at the hot surface of the tube, and, therefore, this hot surface should be increased greatly without necessarily increasing the wet surface. This has been done in some boilers by fixing projecting pieces or rings of angle iron inside the fire tubes to increase the heated surface, and has resulted in a considerable improvement in heat transfer.

The second method depends on the fact that a square foot of heating surface at right angles to the gas flow is about four times more effective than a similar surface at 45°, and about eight times more effective than a similar area parallel to the gas flow—at ordinary velocities of gas. Deflectors or retarders, of one kind or another, are put into the boiler so as to cause the gases after they have been fully burned to impinge on the tubes as directly as possible.

A third method, and probably the one most commonly used, is to put surfaces of brick or other refractory material in the boiler in such a way that the flames play upon them. These surfaces are raised to a high temperature and transfer the heat by radiation to the boiler tubes. Such surfaces, in order to give the greatest effect, must face the boiler tubes squarely, and must be as near as possible to these tubes. It is quite easy to heat surfaces at right angles to the line of gas flow, but usually very difficult to heat surfaces in the required position, as they generally have to be parallel to the gas flow.

The transfer of heat by radiation becomes much more rapid in proportion as the difference between the temperature of the two bodies concerned increases. From Stefan's law that the amount of energy radiated is proportional to the difference between the fourth powers of the absolute temperatures of the hot body and its surroundings we can deduce the following table:

Difference between Hot Body and its Surroundings	Proportional Am't of Heat Radiated
100° C. to 0° C.	1
200° "	3.3
400° "	12.
600° "	26
800° "	45
1,000° "	70

This table shows the necessity of raising our radiating surface to the highest possible temperature; and this again points to the use of the highest possible gas or air pressure in our burners in order to shorten the flame and make it more intense.

Rapid Gas Travel

A fourth method depends on the theory that the difficulty of heat transfer from gas to metal is caused by a thin layer of cooled gas, which adheres to the surface of the metal and acts as a non-conductor. The stream of hot gases is made to scour very rapidly the surface of the tubes, and in this way the cooled gas is swept away and fresh hot gas is constantly applied. Very rapid heat transfer has been obtained by this means. In Nicholson's experiment a cylinder 10 ft. long was put into the flue of a Cornish boiler so as to leave a passage between cylinder and flue wall of only 1 in. all round. These gases were drawn through this passage at a velocity of 330 ft. per second by a high suction, probably 20 in. water-gauge. They were reduced in temperature from 1,260° C. to 425° C. in the passage, giving up sufficient heat to evaporate 36 lb. of water per sq. ft. of the tube per hour.

The author has had no experience with the Bonecourt boiler, but it is claimed by the makers that the heat is taken out of the gas by means of surface combustion on blocks of refractory material in the tubes, and that the heat is transferred by means of radiation from this material. Whether or not there is any surface combustion in the process as carried on in their latest boilers, the author thinks it likely that the high velocity of the gases through the tubes, in close contact with the walls and heating the refractory blocks, may be sufficient to account for the evaporation per square foot claimed. The suction required—16 in. water-gauge for the larger evaporations, equivalent to a velocity of about 250 ft. per second—would seem to bear this out. Unfortunately it is a costly matter to get these high suctions for the very large volumes of hot gas with which we have to deal in boiler firing.

It will be noticed that each of these methods involves either the use of power or the insertion of some obstruction in the boiler. There is no doubt that boiler users object to have any kind of brick erection inside a flue, as it may burn away and require renewal, and it must be removed to clean and inspect the flue.

The author considers that for existing boilers the method of increasing the heating surface by the use of some kind of metal fitting in the flues is the one least open to objection. In regard to the use of power for forced draught or suction, it must always be remembered (although it is more usually forgotten) that such power is a charge against the boiler and that its costs must be deducted from the efficiency of the boiler before the net efficiency of the latter can be brought out. In some cases the power involved is quite small. To put the gas—or air—under 2 in. pressure, in the case of blast furnace or producer gas, requires power which would only reduce the boiler efficiency by 1½ to 2 per cent., whereas the additional efficiency attained may be from 10 to 20 per cent.

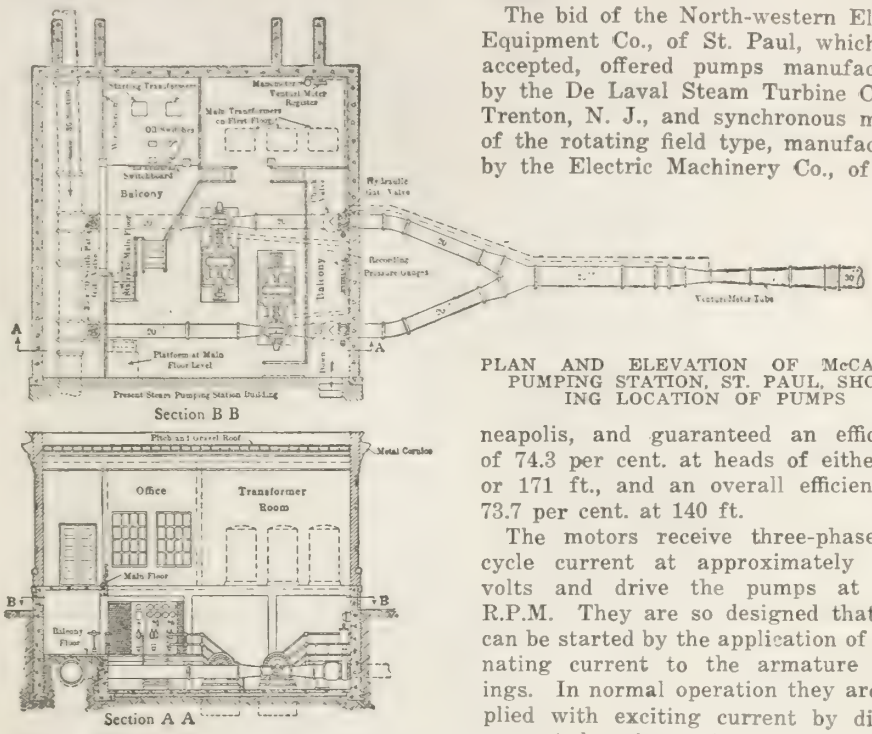
Lancashire Boilers

Boilers of this type are used very largely, and have to be utilized in the best way possible for gas firing. It is a pity that 3-flue and 5-flue boilers are not more often used, as they not only give a larger heating surface, but also allow of smaller volumes of gas being burned in each flue. With smaller volumes of gas it is easier to burn the gas with a small excess of air. A disadvantage of the Lancashire boiler when gas-fired in any of the usual ways is that the fall of temperature in the gases from one end of the flues to the other is not sufficient to set up good circulation of the water, as is done by the intense local heat of the fire when the boiler is hand-fired. In spite of all that is said against gas-fired Lancashire boilers, they will continue to be used and, in the author's opinion, successfully and economically used. As to the output to be got from these boilers, the author has experience of regular evaporations of over 9,000 lb. per hour from and at 212° F. from ordinary 30 ft. x 8 ft. boilers, both with producer gas and with blast-furnace gas. If we notice that the evaporation of 9,000 lb. per hour, i.e., nearly 10 lb. per sq. ft. of heating surface, corresponds very closely to the evaporation per square foot claimed for the Bonecourt boiler at the lower suctions, and that this evaporation is far higher than what we should expect from a water-tube boiler, we may develop a greater respect for the much maligned Lancashire boiler.

HIGH EFFICIENCIES SHOWN BY MOTOR-DRIVEN WATER WORKS PUMPS

MANY pumping problems are most conveniently solved by electric-driven pumps. Such pumps constitute a peculiarly desirable load for central stations, as they operate either at full load continuously, or in some cases are operated only during periods of light load, thus helping to fill up the "valleys" in the load curve.

Where centrifugal pumps are operated by power purchased through a meter, careful attention is likely to be given to efficiency, as a few p.c. in efficiency will in a short time amount to more than the cost of the pumps. The figures showing efficiency and other characteristics of two 12-in. motor-driven centrifugal pumps herein given are taken from a report made by Mr. J. W. Kelsey, principal asst. engineer, to Mr. G. O. House, general superintendent, of the St. Paul Water Dept., and relate to equipment recently installed at the McCarren Pumping Station.



PLAN AND ELEVATION OF McCARREN PUMPING STATION, ST. PAUL, SHOWING LOCATION OF PUMPS

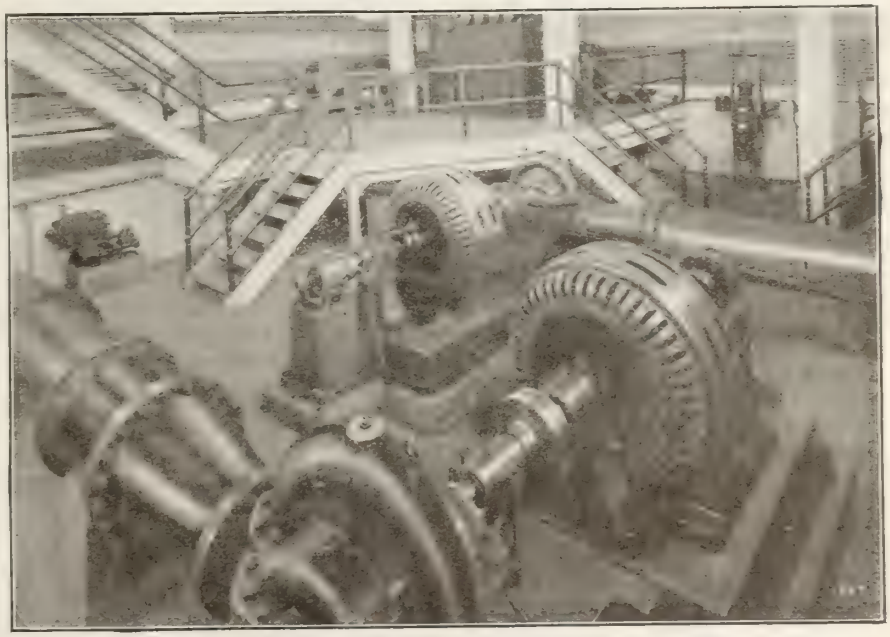
The specifications required that each unit should be guaranteed to deliver not less than 5,000 U.S. gallons per minute against a total head of 171 ft., and not more than 5,500 gallons per minute against a total head of 158 ft., the overall efficiency from "wire to water" to be not less than 72 per cent. when pumping continuously at either of the heads and deliveries. It was further required that when delivering against a reduced head of 140 ft., the motor should not be overloaded.

The bid of the North-western Electric Equipment Co., of St. Paul, which was accepted, offered pumps manufactured by the De Laval Steam Turbine Co., of Trenton, N. J., and synchronous motors of the rotating field type, manufactured by the Electric Machinery Co., of Minneapolis, and guaranteed an efficiency of 74.3 per cent. at heads of either 158 or 171 ft., and an overall efficiency of 73.7 per cent. at 140 ft.

The motors receive three-phase, 60-cycle current at approximately 2,200 volts and drive the pumps at 1,200 R.P.M. They are so designed that they can be started by the application of alternating current to the armature windings. In normal operation they are supplied with exciting current by directly connected exciters of 1¾ kilowatt capacity.

The pumps are of the De Laval single-stage double-suction volute type, having 12 in. suction and discharge nozzles. No diffusing vanes are used.

After installation both units were subected to very complete tests to determine both efficiency and head-capacity characteristics. Before the official tests were run the impellers had been turned down slightly in diameter, due to the fact that the motors were operating at 20 R.P.M. above rated speed.



DE LAVAL MOTOR-DRIVEN CENTRIFUGAL PUMPS. CAPACITY 5,000 GALLONS PER MINUTE AGAINST 171 FT. HEAD.

Before beginning the test, the pressure gauge of each pump was taken off and calibrated on a dead weight testing instrument, and then replaced, the pump stopped and the static head of water determined by finding ahe elevation of the center of the gauges and the elevation of the water in the high service reservoir. The head determined from the elevations was found to agree with the calibration obtained with the dead weight testing instrument. The readings of the suction gauges were also checked against elevations in a similar manner and found to be correct. As they registered zero with no pressure and as the variation in head was never more than 10 ft., it was assumed that readings of the gauges between zero and 10 ft. would be proportional.

The quantity of water delivered was measured by a 30 in. by 13 in. Venturi meter, supplied by the Builders Iron Foundry Co., of Providence, R.I. The recording instrument supplied with this meter includes an indicating dial, a recording card and an intergrating counter, but in order to verify the accuracy of its readings an indicating mercury manometer was also connected to the pressure pipes of the Venturi tube.

The electrical measuring instruments were checked and calibrated subsequently by comparison with standard instruments by representatives of the Northern States Power Co. In running the test, the head against which the pumps worked was controlled by means of a hydraulic gate valve on the discharge side of the pumps. After throttling the gate valve, no readings were taken until all instruments had ceased fluctuating, after which two or three readings were made and averaged, if any variations were found. Observations were made with the pumps operating under four different heads, covering a wide range of delivery.

The results obtained on the official test are shown in the tabulation given below. In computing the efficiencies of the pumps alone, motor efficiences, as obtained on tests of the motors by the University of Minnesota, were used. On motor No. 403,115, the following efficiencies were obtained:

Full load 95.5 per cent. ¾ load 94.9 per cent., ½ load 93 per cent. Motor No. 403,129 gave the following results: Full load 95.3 per cent., ¾ load 94.6 per cent., ½ load 92.5 per cent.

The test results of the units show the variations in head and capacity at constant speed together with electrical horse-power input and overall efficiencies. The efficiencies obtained on these pumps are quite high, considering the comparatively small capacity and the high head. Many builders would advocate the use of diffusing vanes for such conditions, which, however, would make the pump more expensive and complicated without any gain in efficiency. The efficiencies are further very high over a considerable range in capacity. Take for instance, pump No. 25651, which at a capacity of 6,527 G.P.M. shows an efficiency of 81.8 per cent. and at 4,097 G.P.M. an efficiency of 77.0 per cent., or for a reduction in capacity of about 37 per cent., there is a reduction in efficiency of only 5.9 per cent., which must be considered very good for a centrifugal pump.

The pumps deliver slightly more than 5,500 G.P.M. at 158 feet total head, but this was not at all objectionable, due to the fact that the efficiency was very high also at low heads, which in this particular case was of great advantage as can be seen from following quotation from the official report:

"As to the quantity of water pumped, it will be observed that it more than meets the requirements of our specifications. The clause in our specifications limiting the quantity of water to 5,500 gallons per minute when working against a head of 158 feet was inserted to insure a high efficiency at this pressure. It was our belief that the maximum efficiency would be obtained when pumps were working against a much higher head. Fortunately, however, the reverse is true, and our pumps are delivering a greater quantity of water with a higher efficiency than was anticipated at the lower heads.

"As stated before, the friction loss in our force mains is less than computed, with the result that our operating head is somewhat lower than provided in our plans, which explains one of the main reasons for reducing the effective diameter of the impellers. The consequence is a greater quantity of water at a higher efficiency against our prevailing dynamic heads."

TENDENCIES IN BOILER-ROOM PRACTICE

DIFFICULTIES attending power house operation during the past year have multiplied rapidly due to shortage of labor and the necessity of using indifferent fuels. Further aggravation was caused by the unprecedented demand for power and the impossibility of securing deliveries of new plant. Writing in the "Electrical Review" regarding power practice in 1917. I. L. Kentish-Rankin states that the situation has gone from bad to worse. Managements that once chose laborers, when they should have selected chemists, now have to take what is available and to try and keep it. Labor has migrated to more pleasant and better callings, and it is suggested that greater attention to the establishment of more comfortable conditions of working will be necessary.

Men must not be called on to do work which can be effectively accomplished by machines, and more attention must be paid to the ventilation and lighting of the boiler-room. The underfeed stoker has proved of very great advantage in the conditions of last year, since it permits of very high rates of firing, enabling the output of the boiler to be increased in continuous running to 2¾ times the normal rating. Since additional boiler capacity has been practically unobtainable it has been necessary to take overloads by forcing the boilers, and underfeed stokers are now being used with fuels for which the chain grate type was previously considered essential. This has led to much trouble from clinker, but the dilemma before the station management was the adoption of a stoker which could at need work at four times its normal rating, but was liable to form troublesome clinker, or to use another type which gave little trouble in this regard, but could not be forced much beyond its normal working capacity.

The clinker troubles have been aggravated by the necessity of using coals containing as much as 25 per cent. to 35 per cent. of ash and by the high temperatures resulting from the intense forced firing. As a result, ash pits have often proved of insufficient capacity, and with exits smaller than the lumps of clinker to be removed. The size of these lumps has been a source of much trouble. They are not easy to break, and the work is unpleasant. Mechanical ash conveyors which were formerly satisfactory have proved unequal to the new conditions. Moreover, there is much more trouble nowadays in the final disposal of furnace refuse. It is being found profitable to increase greatly the number of instruments in use in the boiler-room. The demand for CO_2 recorders, steam and water meters, is unprecedented, and steps are being taken for the more careful instruction of the staff in their maintenance and use.

Kingston.—At the meeting of the City Council it was decided to purchase engines to supplement the power supply for their street railway system. It was anticipated that a ten-minute service can now be given.

ELECTRICITY FOR THE BRITISH NATION

ONE of the most far-reaching suggestions towards national reconstruction is set forth in an interim report made to the British Ministry of Reconstruction by the Coal Conservation Sub-Committee. The report is now issued to the public with the following preface by Dr. Addison:—

"Minstry of Reconstruction.

"This report, which was presented to the Reconstruction Committee, is issued for the information of the public, and in the hope that the very important matters with which it deals may receive adequate consideration at the hands of all those likely to be affected by its proposals.

"It will be observed that important issues affecting municipalities and public bodies are raised in the report, and they will be explored in all respects by the Government before any action is proposed to Parliament upon the subject. In its legislative aspect the whole matter is being investigated by a Committee appointed by the Board of Trade, and presided over by Sir A. Williamson, M.P.

"(Signed) C. Addison."

The Sub-Committee proposes briefly, to supply all our industries with electrical power generated at big "superpower stations," not more than 16 in number for the whole country, and to eliminate or combine all smaller stations.

The primary object of the scheme is to economise our coal supplies. The amount of coal used in the United Kingdom for the production of power is 80,000,000 tons, at a cost of, say, £40,000,000 at the pithead. The Committee confidently states that, by an up-to-date and national scheme of electrification, 55,000,000 tons of this (£27,000,000 a year) could be saved. This, with a saving of the by-products now wasted by the burning of coal in open grates and boiler furnaces would effect a national economy of £100,000,000 a year.

Economy Possibilities

The most economical way of obtaining power from coal on a large scale is by generating electricity from it. The coal now used, says the Committee, would, if used economically, produce at least three times the present amount of power. An increased use of power is of the highest importance to the future prosperity of the country. It is the best way to increase the net output per head and, therefore, the prosperity of the worker. "The best cure for low wages is more motive power."

In the United States the amount of power used per worker is half as much again as in the United Kingdom. Leaving out of consideration workers in trades where the use of power is small or even impossible, it is probably nearly double what it is here.

It has been settled conclusively during the past 15 years that the most economical means of applying power to industry is the electric motor. In the factories put down for the production of munitions during the war, 95 per cent. of the machinery is driven by electricity, and it is only a question of time for all power to be applied in this way. The problem is not how to apply electric power but how best to generate it.

The development of electricity in this country has been hindered by the numerousness and the smallness of the electrical undertakings. At the present time the supply of electricity in Great Britain is split up among about 600 companies and municipal undertakings. The average generating capacity of such of these undertakings as possess power stations is only 5,000 horse-power, or about one-fourth of the capacity of one single generating machine of economical size, and about one-thirtieth of that of a power station of economical size. Technically and commercially the big generating station is admittedly the best.

Proposed Reform Scheme

The reform proposed by the Committee is to supersede all these small undertakings by laying down throughout Great Britain main trunk lines to be fed by some 16 "superpower stations."

The generating machines in these stations should be of large size, not less than 20,000 horse-power each. In more important industrial districts machines of as much as 50,000 horse-power might be used with even greater advantage. The generating station s should be on large sites with ample coal and water transport facilities. It is contemplated that at each generating station by-products might be extracted from the coal before it is used for the production of power, and that various electro-chemical processes which are essential for this country should be carried on near by. The sites for the stations must be outside, not inside towns. This would improve the health of the great industrial centres by the reduction of smoke, and would relieve the congestion of the railway lines in their neighborhood by practically abolishing the carriage of coal.

Various forms of electricity supply authority, both public and private, are considered. but the committee, on the whole, favors private enterprise. They are "impressed with the special need for initiative and resource in the management of the business of power supply, and they are of opinion that the freedom of range and keenness which are distinctive of private enterprise will be found to be in a high degree conducive to the fullest measure of success."

The 16 great power authorities, whether private companies or public bodies, would be controlled by a National Board of Electricity Commissioners. Existing plants would be handed over on equitable terms to the new authorities. In addition to the main generating stations, subsidiary generating plants would be set up wherever there was surplus gas or waste heat, as at blast furnaces and coke ovens, and the electricity so generated would be fed into the main-trunk system. In the same way, waste coal, which is not at present worth the cost of carriage, and is, therefore, left at the pits, could be used on the spot.

Existing Examples

There already exists in this country a practical example of centralised production of electricity for a large area. The north-east coast district, rather larger in area than Lancashire, is served by a group of power companies from one inter-connected electrical system. The population of this area is less than that of Lancashire, and the area is, therefore, less advantageous for electrical supply. But, whereas in Lancashire, with its multiplicity of electrical undertakings, the price per unit for electric power varies from a penny to twopence or more, the average price paid in the north-east coast district is less than a halfpenny a unit, and the use of electric power per head of population is three times as great. A great saving of coal and reduction of smoke has resulted. Apart from the electric-power companies' consumption, practically no coal is burnt on the Tyne for power purposes, except by the railways and some collieries. The Tyne shipyards may be said to have adopted electricity to the exclusion of all other forms of power. As a result of the adoption of electric traction on the suburban railways, the traffic facilities of the district are greater than those of any other district of similar size. New industries have been established in the district, solely on account of the cheap electric power available. Waste heat and gases have been extensively used for the production of electricity, so that electric power is produced as a by-product of two of the largest local industries —the making of pig-iron and coke. These local generating stations are commonly called "waste-heat stations." The first was erected in 1905, and there are now 11 at work.

The committee foresees, as a result of a national system of electric-power supply, a great increase of the use of electricity for all purposes, with many advantageous results. Factory chimneys would gradually disappear. Railways would be electrified, even for the haulage of goods trains. Smoke would disappear from our towns and coal waggons need run no farther than to the electric-power stations. Electric light would be cheap enough for the poorest, and there would be a large increase in the use of electric heat and power for household purposes.

Extreme Importance

As showing the importance of the scheme the report says: "It is scarcely possible to exaggerate the national importance of a technically sound system of electricity supply, because it is essentially one with the problem of the industrial development of the country."

"The development of such a power system may be likened to the development of the railways of a country, and it is just as impossible to secure economical power generation and supply by each municipal area working independently (which is the position to-day) as it would be to have an efficient railway system if each municipal area owned its own lines

BUSINESS ON AN HONORABLE BASIS

THE "greasing" method of doing business is not dead. It's been killed as many times as the Turk cruiser "Goeben" has been sunk, and as many executions have been performed on it as are registered up against the iniquitous practice of political patronage.

But it has a powerful come-back. Its recovery is always a little better than its recoil.

When one man or class of men are ready to drop it, there's bound to be another set coming along to pick the old thing up.

However you look at it, it's a poor way to do business. An article that can't travel on its merits is expensive at any price.

The system of paying a man to get a certain line of goods used or introduced into a factory where he occupies a responsible position is a miserable subterfuge for clean methods.

Sooner or later the thing will play out. The straw and wood will burn up and your greased organization will go down in such a heap that its knees will be driven up to its chin. After that the old cripple can never be straightened out again.

Whether you are selling, buying or manufacturing, go it clean. Get your business methods up level with your head where you can look them straight in the face. Make certain that your business is done in such a way that you won't have a brown tongue the day after.

Don't make the mistake of thinking that a little bit of temporary success can be worth as much as a permanent organization, built on legitimate and honorable lines.

And don't forget that there are very, very few firms who want to do business on the "grease" plan. They want to spend a dollar and get a dollar's worth of real value in return. That, and nothing else, is the real basis for successful and lasting business relationships.

BUYING REAL COAL

A BILL is now in the Ontario Legislature to force dealers to weigh coal on municipal scales or by municipal officials. J. A. Pinard of East Ottawa is sponsor for the measure, and it has been advanced to its second reading.

The chief objection will come from dealers who will not want to cart their coal to civic scales when delivery is to be made in an entirely different section of the city. It will not be practicable to have a civic official to check up the weight at the scales of each individual dealer.

There is a great deal more point and purpose to an announcement contained in the United States Official Bulletin of March 9. The drift of this is that bituminous coal must be mined clean or sold for less than the fixed price.

H. A. Garfield, United States Coal Administrator, has given very wide powers to the district representatives of the fuel administration. In fact, it looks as though they had really been constituted a court of last resort by the fuel administrator. Where the coal in any part of the mine is found to be naturally of such character as to be unfit for market, judging from the usual standard of the district, the district representative may order the mining suspended in said part or parts of a mine until or unless proper cleaning methods be adopted.

Not only so, but the inspectors are authorized to condemn at the mines "any coal loaded in railroad cars which in their judgment is not properly prepared. . . . If the district representative approves the inspection report he shall so notify the operator at once; in which case, unless the operator unloads and reprepares the rejected coal, the consignee shall be permitted to deduct 50 cents per ton from the authorized price for the grade of coal." Of course, the consignee, if he wishes, may go ahead and pay the full price, although this looks like a long chance once the fuel inspector has condemned the coal.

The fuel scarcity that Canada has passed through has brought to many a Canadian home a quality of coal that never could get past in ordinary seasons. This, of course, refers particularly to anthracite coal.

Association and Personal

Howard Taylor, who for some years has been chief electrical and mechanical engineer of the Spanish River Pulp and Paper Co.'s plants, with headquarters at the Soo, has resigned to become consulting engineer with the Dayton-Wright Aeroplane Co., at Dayton, Ohio.

C. N. Schrag, of the Bawden Machine Co., is leaving there the 1st of May, to go into partnership with O. W. Meissner, manufacturers' agent, Montreal, handling a line of railroad, pulp mill, marine and engineering supplies. Mr. Schrag will open a Toronto office in the Royal Bank Building.

James M. Smith has arrived at Fort William to take charge of the shipbuilding and of the plant of the Canadian Car and Foundry Company, which is under contract to turn out twelve trawlers for the French Government before the close of navigation. Most of the steel for their construction has been assembled at the works, and the building in which they will be built is almost completed.

Frederick Field, engineer superintendent of the city filtration plant, has written to the Montreal Board of Control asking for indefinite leave of absence so that his services may be available for the United States Government. In his letter he says that he has received a request from the chief engineer of the Housing Department of the U.S. Shipping Board to accept a position in Washington.

W. H. Winterrowd, formerly assistant chief mechanical engineer of the Canadian Pacific Railway, has been appointed chief mechanical engineer in place of W. E. Woodhouse, who has asked to be relieved of that position. Mr. Winterrowd had a university training in addition to practical experience in the shops and in various branches of the mechnical departments of the Pennsylvania and New York Central railroads before he joined the Canadian Pacific Railway six years ago. He was brought to Montreal by H. H. Vaughan, now vice-president and general manager of the Dominion Bridge Co. It is an interesting coincidence that Mr. Vaughan was exactly the same age, namely, thirty-six, when he himself was appointed chief mechanical engineer of the Canadian Pacific Railway.

J. B. Brophy, C.E., who was chief engineer of Cape Breton section of the Intercolonial Railway from Grand Narrows to Sydney during the construction in 1889 and 1900, and who was resident engineer for the past two years of reconstruction of St. Peter's Canal, and lately engineer of railways and canals at Cornwall, died after a short illness of pneumonia at Ottawa. The late Mr. Brophy was married at Sydney to Ella, eldest daughter of the late J. H. Hearn, K.C., who predeceased him four years ago. He leaves two daughters. The late Mr. Brophy never fully recovered from the loss of his son, Lieut. "Don" Brophy, of the Royal Flying Corps, who was killed while on duty on the east coast of England at Christmas in 1916. Col. Bob Low is a brother-in-law of the late Mr. Brophy.

THE PASSING OF GERMAN INDUSTRIES

By C. T.

ACCORDING to authoritative information which has filtered through from Germany, with much weight behind it, there is much of interest in the condition of Germany's engineering and allied industries. The manufacture of an innumerable list of machine tools is being slighted and thus other industries are gradually going by the board. The manufacture of rails and railway equipment is below requirements so the magnificent net of German railways is going into a state of magnificent ill repair. The fabrication of shrapnel has replaced the manufacture of lace machines and looms. The fabrication of submarine parts has replaced the manufacture of locomotives, typewriters and sewing machines. The fabrication of shells and cannon has cut down the manufacture of agricultural implements. All the strength of the factory and forge is being sucked into the never-satisfied munitions business, the tentacles of which, furthermore, are continually drawing away the life-blood of other varied industries.

The steel industry has become a thorough-going war industry, one feature of which is the continued manufacture of imperatively needed staples. This industry has been so terribly pushed by the primary demands of the gigantic war business of the Central Empires and Turkey that it has not been found possible to produce sufficient rails and rolling stock for the railways, important as are these battle nerves of Germany in her efficient game of war. The Krupp people have established branch furnaces and forges in all parts of the country, likely with the idea of minimizing enemy opportunity for crippling the shell and cannon production. Furnaces have been operated for the Krupp works in France, Belgium and Asia Minor. Asia Minor is being developed into a metal treasure-trove for Germany and many millions of marks have been, and are being expended in the building up of mining properties there.

There is no longer a scarcity of metals in Germany. Copper is plentiful. Nickel mines in Anatolia are yielding considerable outputs. Serbia, Rumania, and Anatolia are now furnishing large supplies of copper.

Before the conquest of Serbia the metal outlook in Germany was dark and dreary. They stripped the roofs of large buildings and factories of their copper and conducted a painful house to house survey of the copper and nickel stores of the Empire. Ornaments, kitchen utensils, heirlooms, statues and bells, all went into the munition melting pots; and the kitchenware, at least, was replaced by coarse pottery.

The whole metal industry of Germany is concentrated on war, on the output of shells, bullets, armor plate, cannon, submarine parts. Every other business interest of the Empire is subservient to the demands of this industry. It is maintaining an atmosphere of hopeless hectic rush, and its activity and prosperity are surely ruining the country.

OPERATOR ORGANIZATIONS

British Columbia Association of Stationary Engineers, Vancouver.—Subordinate Lodges at Vancouver, Victoria, New Westminster, Cumberland, Merritt, and Fernie.

North-West Association of Stationary Engineers, Edmonton, Alta.

Manitoba Association of Stationary Engineers, Winnipeg.

Canadian Association of Stationary Engineers, Hamilton, Ont.—Subordinate Lodges at Montreal, Toronto, Hamilton, Ottawa, Brantford, Guelph, Kitchener, Chatham, Ont.; St. John, N.B.; Owen Sound, London, Stratford, Belleville, Kingston, Sudbury, St. Thomas, North Bay, Port Arthur, Sarnia, and Windsor, Ont. The executive officers of the C.A.S.E. Grand Lodge are as follows:—

Past President—W. G. Forbes, Montreal, Que.
President—R. F. Gofton, Kitchener, Ont.
Vice-President—Wm. Cooke, Belleville, Ont.
Treasurer.—A. W. Heath, Hamilton, Ont.
Conductor—S. Balmfirth, Toronto, Ont.
Doorkeeper—George Moll, London, Ont.
Secretary.—John H. Hale, Hamilton, Ont.

The first test of shrapnel was made in England 112 years ago, when a committee of British army men reported favorably on the invention of a fellow officer, Henry Shrapnel. Shrapnel was .rst employed in warfare in 1806 and fully demonstrated its explosive usefulness.

The Operators' Point of View

UNION VS. C. A. S. E.

By R. S Wright.

IN the following article it is far from my intention to condemn any organization, because they may be right and I wrong.

It is one of the greatest fallacies of man at the present day that the individual believes himself right and every other person wrong. One of the greatest wonders of creation is that no two persons are alike in this world, and before condemning our brother's views we ought to pause and consider the merits and demerits on either side.

My object in writing is because I have been informed that the Stationary Engineers' Union condemns or despises the C. A. S. E., and I beg to be permitted through this medium to set forth some facts of my experience with the Amalgamated Society of Engineers in the Old Country.

For a start, I believe that every branch of industry ought to be organized; union is strength, but we may be united for peace or we may be united for war, and I am proud to say that the C. A. S. E. are united for peace, peace and harmony between master and man. We are desirous of educating ourselves to make us better men to our employer and show him we are worthy of consideration. That this is appreciated by a vast number of employers throughout Ontario is proved by the fact that they are honorary members of the C. A. S. E.

I will now endeavor to give an account of the union for war. It was connected with the Amalgamated Society of Engineers in the Old Country some years ago. The engineers in Belfast, Ireland, demanded an increase of a farthing an hour (about 5c per day). This demand was refused by the employers because work or contracts were not so plentiful as might have appeared on the surface, so the engineers in Belfast declared a strike. Now, as we were all in the same union we had to come out all over the British Isles (coercion) whether we wanted to or not. Now, an engineer there must belong to the union before he can get employment (coercion again), and an employer is not allowed to employ a blackleg (coercion).

As I have already stated the employers were in a good position to withstand a strike and any pressing orders they may have had on hand were handed over to Germany and completed there. The money we paid Germany on that occasion and on various other occasions helped to make guns and ammunition to blow our brains out.

How the Community Have to Pay for the Fear of Strikes

An employer continually under the threat of a strike must be prepared for that contingency and in consequence must charge more for his contracts, which the strikers as well as others of the community have to pay for indirectly.

He must pay the standard society wage to the inferior employee as well as to the efficient employee, so therefore the man who does the work gets no more pay than he whose only thought is stopping time.

But the worst feature is yet to come. We remained on strike for nine weeks, during which time our society funds got exhausted; our homes were reduced to beggary, and I had seen poor mothers going round the scrap barrels in the wealthy localities to see if they could procure a crust of bread for their starving children. Such a strike affects not engineers alone but also much unskilled labor which has no society funds to depend on.

Now, at the end of the nine weeks we resumed work at the same wages we were receiving before the strike, and a great many of our members did not get work at all, so this ends a chapter of my career I never wish to experience again.

It does not avail an employee to kick against his employer; it is certainly kicking against the pricks and the workman generally gets the worst of it in the end. Also, if for instance the railway employees go on strike the community have to suffer for it in the form of increased tariffs, etc., and the striker in the end must pay his share of that higher tariff rate in the form of a higher cost of living. It all comes back on the working man in the end.

Now, the much better way is to join a society, say the C. A. S. E., who will educate you to a high state of efficiency and make you a person your employer does not want to part with, then the wages will come automatically.

In conclusion, I will state I don't believe any sensible employer will refuse a good man the wages he is worth. So look to your own defects first. Then you can pack all your troubles in an old kit bag and smile, smile, smile.

HINTS ON MAKING WATER TUBE JOINTS ON STEAM BOILERS

By S. Balmfirth

ONE of the disadvantages of water-tube boilers is the number of joints that have to be cleaned and remade each time the boiler is cleaned and overhauled. The writer offers the following suggestions for shortening the time used in doing this job.

To grind the faces of the caps the writer had an arbor made, to fit the drill press with the end turned to a short stumpy cone. This cone gave sufficient

FIG. 1. ARBOR USED FOR TRUEING UP THE FACE OF THE NUTS.

friction to turn the cap on the emery cloth laid on a faced plate on the drill press table. To avoid using too much emery cloth oil and emery powder were placed on the cloth. The use of the cloth, emery powder and oil made a quicker job than the emery powder and oil which were first used alone on the faced plate. If the cone is made short enough it can be used for grinding both face and back of the cap.

To grind the face of the nut a box wrench was made out of a pipe coupling and a bushing was screwed in one end

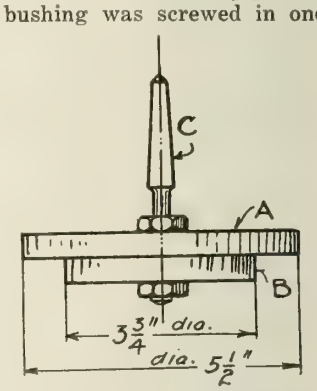

FIG. 2. ARBOR USED FOR GRINDING AND TRUEING HEADER CAPS.

for mounting on an arbor made for a drill press.

To clean the bolt thread, a revolving steel wire brush is used. This cleans off all scale and dirt and saves running a die over the threads.

If it is necessary to take a cut off the face, an arbor made as shown in fig. 1 saves considerable time. A is a jamb nut run up to the end of the thread and then faced up. To use this arbor the back of the cap is faced up in the lathe and then put on the arbor and held back against A with another nut.

The above hints are all intended for B and W boilers.

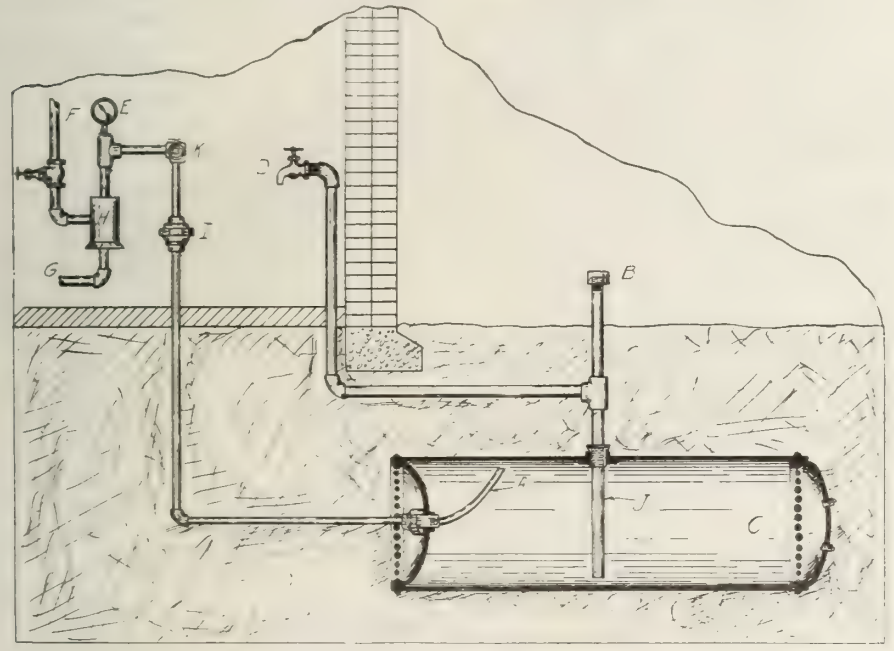
Another idea which saved considerable time was used in cleaning the tube holes in the headers. Fig. 2 shows a disc made big enough to cover the tube, B is made to go inside and C is a small bolt, the outer end having a square tapered shank for a brace. By loosening the nut emery cloth can be placed between A and B and revolved on the tube end to clean it. Emery and oil may also be used with advantage on the cloth. Of course there are the advertised motor driven cleaners for tube ends but these cost real money.

I have sometimes, although I do not recommend the idea, used paper gaskets on the B & W caps but am inclined to think it not very good engineering.

A SINGLE TANK FOR OIL STORAGE

By James E. Noble.

A SIMPLE easily installed outfit for storing gasoline, coal oil, signal oil or other inflammable or light oils or liquids is shown in the accompanying sketch. It will prove useful around large office, manufacturing and apartment buildings,



OIL STORAGE SYSTEM USING SINGLE TANKS.

where they have frequent occasion to use benzine and various other oils and liquids.

Referring to the sketch, C is a 100-gallon galvanized iron range boiler, J is a ¾-in. pipe screwed into the inside of a 1-in. by ¾-in. bushing, B is the filler pipe, D is the draw-off cock.

A piece of ¼-in. pipe is bent and screwed into a nipple, which in turn screws into a bushing in the boiler crown. Care should be taken to have the pipe bend towards the top, as shown, when the nipple is screwed in.

A reducing socket makes connection to a pipe leading to the automatic air compressor H. This air pump is similar to the kind used on beer outfits in hotels. There should be many second-hand ones soon thrown on the market for sale. F is a ⅜-in. city water supply pipe, and G is the waste pipe. The waste water can be run to the boiler room hot well and used in the boilers, thus making the operation of the pump free of cost. E is a pressure gauge, and I a ¼-in. union.

The tank may be filled by removing the plug from the elbow K and pouring in the oil at B. The oil then replaces the air in the tank C, the plug is replaced, and by pumping air into the tank the oil is forced out.

If all underground pipes and fittings are galvanized and given a coat of tar the outfit should last for very many years without any trouble. In every description I have seen of outfits using compressed air a separate air tank is used, but by using the automatic air pump as here described no extra tank is necessary.

OYGEN AND PERPETUAL MOTION

WITH reference to the letter of Mr. S. Bamfirth's in your issue of March 28, in which he expresses strong doubts on the possibilities of using oxygen as a motive force in engines because it is not combustible, I would ask Mr. S. Bamfirth since when have we been dependent on combustibles for use in engines as a motive force? Steam and compressed air are not combustibles, neither is gasoline until mixed with air, that is nitrogen and oxygen. Judging from Mr. Bamfirth's letter I presume he is not an engineer, or perhaps he has not given the matter about which he writes much attention; the following remarks may be of interest to him and be the means of removing some of his doubts.

Oxygen forms about one-fifth of the atmosphere and can be reduced to a liquid state. Hydrogen can also be reduced to a liquid state; both these elements expanded like steam would drive an engine in the same way. Oxygen mixed with hydrogen is an explosive, and, I presume Mr. Gallacher, the inventor of the machine for extracting oxygen from the air, would use it much in the same way as gasoline is used, combining hydrogen with oxygen by an intake arrangement similar to a carburettor, in doing which he would only be following in the footsteps of other experimenters. It is a simple matter to drive an engine by this means, the real difficulty is to harness these elements to make the use of them safe. Expansion is too rapid, and the difficulty of admitting only what would be a safe quantity of gas into a cylinder has not been overcome; until this has been done, the experimenter is in greater danger of blowing his head off than he is of failing to obtain power. Similar reasons have retarded the use of acetylene gas. In conclusion I might point out that oxygen and nitrogen, "another element of the atmosphere," are the active elements of the most powerful explosives, including nitro-glycerine. Yes, there is plenty of push behind oxygen used as a base like gasolene.

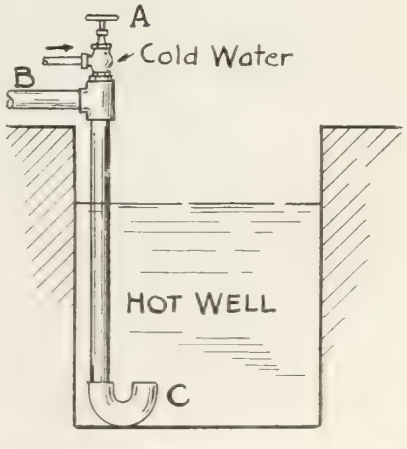
UNION ENGINEER.

Labor Temple, Toronto.

SUCTION PIPE KINK

By J. E. Noble.

The hot well is still in use in many small plants and when the returns are very hot the pump will refuse to pick up the water on account of the steam. The way one man overcame the trouble is shown in Fig. 1. A ¼-inch cold water pipe was connected to the pump suction pipe, this pipe with a ¼ angle valve is shown at A. The pipe C is the suction pipe from the pump. When the returns are very hot, say 190 deg. Fahr., the ¼ angle valve is opened a turn and the



HOT WELL SUCTION ARRANGEMENT.

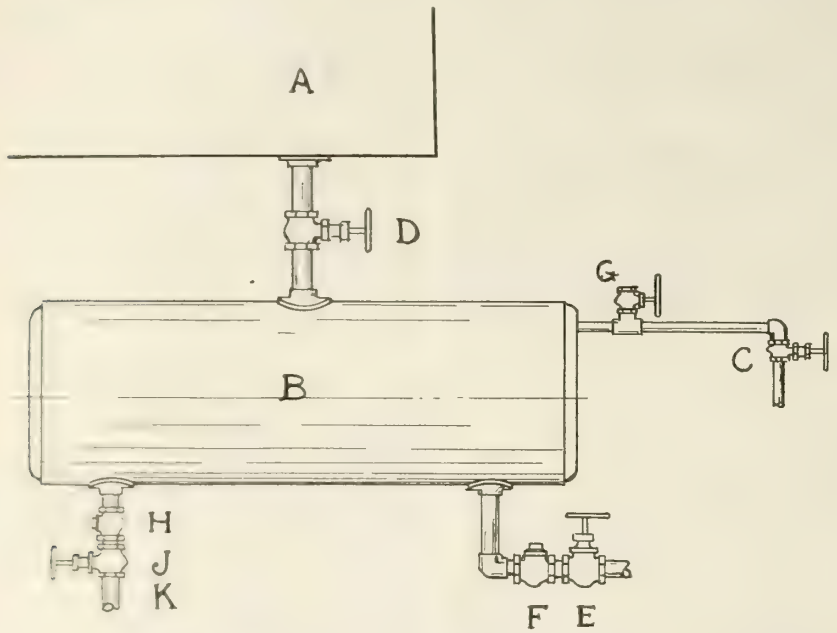
pump works like a charm. Sometimes dirt will collect at the bottom of a hot well. It is a good plan to place return bend on the end of the suction pipe, as shown at B. A strainer can be added if desired, but is hardly necessary. The bend also provides a good support for the upright pipe. The ¼-inch cold water pipe idea can also be used where metering heaters, or where ordinary exhaust steam water heaters are in use, as it is quite possible that the same trouble will be found here, especially if the heaters are on a lower level than the pump.

A GRAVITY BOILER FEED

By J. E. Noble

I HAVE heard it said that the arrangement shown was often used as a boiler feed in the old days, and that in some remote "wilderness" plants it is not unknown at the present time.

The tank B is placed several feet above the steam boiler. Tank A is supplied by rain caught from roofs; when this supply fails it is carried up or pulled up with a rope and tackle arrangement, or supplied in some other way. C is a steam supply from the boiler, a check valve and globe valve are shown at E and F, which is the supply to the boiler.



METHOD OF FEEDING BOILER BY GRAVITY.

To fill the tank B, close C, open air valve G, and valve D. When the tank is full close G and D and open C and the quantity of water required for the boiler supply can be regulated by the valve E.

By running pipe K to the hot well and attaching check valve H and valve J, water can be drawn from the well to the tank by first filling the tank with steam and then closing all valves except J, as the steam condenses a vacuum will be caused and the water will rise; valve J can be left open all the time.

DOES IT REALLY MATTER?

By W. H. A.

DOES it matter much if a piston does stop or not at reversal and why all this talk on the matter anyway? Any pistons I have ever had anything to do with were too busy doing useful work to bother about stopping at any part of the stroke. There has been more energy, time and space wasted in discussion over this matter than the engine itself expends in getting over either center.

Let's stop all this discussion about this matter and expend that useful energy in a more important way.

For instance, could not we derive more real benefit by using the space for the discussion of the economical use of fuel and thereby keep that much-talked of piston everlastingly on the move? Among engineers this fuel conservation is a serious matter and is getting more serious.

Dont let the chief do all the figuring as to haw to get all the good out of our coal that there is in it. There are many things that he could give his attention to in the betterment of conditions generally if he were assured that there were conscientious men near at hand.

There are many ways in which we could accomplish much in the saving of fuel. For instance, you and I, both assistants perhaps in different plants, are possibly never called upon to wheel or shovel coal and perhaps we look no further than to see if there is a sufficient supply on hand to last over a limited length of time, say until the end of our shift.

To be sure there is no great art in wheeling coal or shovelling it into the furnace. Where the art comes in is in putting it into the right place at the right time.

Different plants require different methods. There are as many different methods as there as plants, nearly, but all methods are, or should be, used to come to a reasonable conclusion, that of delivering at the end of the line the highest possible percentage output. Try to keep that space between output and input as short as possible.

There is a way I've found to work to my advantage, that is to cultivate the acquaintance of your coal wheeler and fireman. Let them know that any effort on their part to secure results is appreciated. I don't mean to hug them after every fire, but just let them see that they are as necessary around the plant as you are.

I have noticed in some plants that there is such a thing as class distinction; that may be all right as to different classes of work, but each class of work is necessary to the other, the coal passer, fireman, oiler, assistant and chief engineer are all necessary to each other and a man can work more satisfactorily all around if he be taught a system derived from the use of reason and common sense.

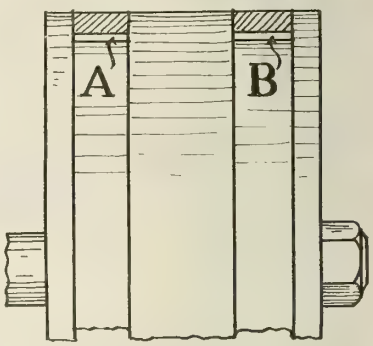
Show them how to do it, why they should do it, and when results come let them share them. This is one way, I think, to save coal. Be sure you know yourself and then teach others the right way. Useful knowledge is that knowledge which you are willing to impart to others.

CLICKING PISTON RINGS

By John Ford

A DISAGREEABLE noise developed in a steam engine, and after careful examination it was decided that the trouble was in the piston rings. These rings were of the snap style on a solid piston with turned ring grooves.

There were no facilities for securing a new ring and a temporary repair was attempted. The old rings were removed and a thin strip of tin placed around the grooves at A and B as shown in the accompanying illustration. The rings were placed over these strips and the piston replaced. No further trouble developed and the noise was removed.



METHOD OF REMEDYING PISTON RING TROUBLE.

ALCOHOL AS A MOTOR FUEL—II.

By J. E. MacCormick.

I have before me some material prepared a few years ago, after considerable study of the subject. Leaving out the "whereases" and the "findings" having the least bearing on the cost of production, together with the various references to literature substantiating the claims made, I quote in part:

1.—In many cases the grain or roots would, if sold, buy gasoline enough to produce as much power as could be obtained from all the alcohol which could be produced from the said grain or roots.

II.—That in some cases the coal required during the process of distillation would, if used in a producer gas plant, yield as much power as could be produced

by the alcohol that same coal would be sufficient distillery fuel for.

III.—That the combination of raw material values as in finding I. and the fuel cost as in finding II. make the production of alcohol for power purposes commercially impracticable except possibly from sugar beets and artichokes (which will be considered later), and in these two instances the value of the resulting pulp as a fertilizer if returned to the soil is probably the strongest claim in favor of the community-still industrial-alcohol proposition.

IV.—That an average ton of sugar beets will run about 14 per cent. sugar, or 280 lbs. of sugar content per ton, and that this amount yields only 17½ (Imperial) gallons, or one gallon of alcohol for each 16 pounds of sugar content, and that, therefore, 1¼ cents per lb. for the sugar = 20 cents per gal. for the alcohol if the expense of refining are the same in each case. Thus, 2½ cents per lb. on the sugar represents 40 cents per gal. on the alcohol possible to obtain therefrom.

V.—That in ordinary gasoline engines one-half more alcohol is required for a given power than is required of gasoline for the same power, while with a specially-devised engine for each they are about equal for power, gallon for gallon.

VI.—That this result is in part due to the economy of B.t.u. owing to the higher compression possible with the alcohol without causing pre-ignition.

XII.—That, considering findings III. and IV. (and choosing from among Canadian products), artichokes alone are a possible commercially practicable source of alcohol for motor fuel in competition with other forms of fuel.

The remaining findings refer to the artichoke phase of the question, which can perhaps be more briefly outlined by quoting from an attached memo. slip. This slip refers to a potato distillery employing two laborers and a foreman and having a capacity for handling 8,000 pounds (4 tons) of potatoes per day. It requires 1 ton of soft coal per day to operate it, and the assumption is that, owing to the similarity in the nature of the roots, it will, if working on artichokes, handle the same weight of raw material, use the same amount of coal, employ the same men, and produce 19 gallons of alcohol per ton of roots, or 76 gallons per day.

Running ten months per year, it will thus require 260 tons of coal and produce 19,760 gallons of alcohol.

The cost of fuel will be 1.316/1000 cents per gallon of alcohol for each dollar per ton the coal costs. Thus, if coal were to go to ten dollars per ton the cost per gallon would be 13 1/6 cents.

The following table, though fragmentary, should be of interest:

TABLE No. 3.

Assumed price of coal per ton	Total cost of coal	Value of 19,760 gals. at 25c	Balance from $4,960 after paying for coal	Assuming said balance is all devoted to paying for the roots	
				Rate per ton	Rate per bushel (60 lbs.)
$10.00	$2,600	$4,940	$2,340	$2.25	6¾ cents
6.00	1,560	4,940	3,380	3.25	9¾ cents
4.80	1,240	4,940	3,692	3.50	10½ cents

worth more than that for pig feed, for instance, especially when there is such a demand for bacon as at the present time. It must be remembered that (a) in the above table no expense except that for coal has been considered; (b) that distillery equipment is expensive, involving a large outlay and large necessary allowance for interest, depreciation, taxes, insurance, etc.; (c) and that wages must also be paid. In fact, when all expenses are paid, the above 7, 10 and 11 cents per bushel, though small already, will be brought materially lower. I think it would be much better to save the money otherwise invested in the plant, and unless these roots were wanted for some other use, let the land be used for some other crop, for some other purpose, say, for instance, wheat to be ground into flour.

If the above 25c per gal. looks below the retail price of gasoline remember that the distillery will be expected to meet wholesale prices.

In the above no allowance has been made for market value of the pulp or slops. Bulletin 410 devotes a few pages to this phase of the subject, which, however, I can not think will turn the scale very much. Distillery men are now "onto" the value of these, and if they saw money in the alcohol motor fuel proposition it's a safe bet they would go into it; but does anyone suppose these men are going to put denatured alcohol onto the market at a price which will compete with gasoline so long as they can get two or three times that amount for it as denatured alcohol for use in the arts?

The article on page 9 of the January POWER HOUSE suggests that if potatoes were sold at 21½ cents per bushel there would be greater profit to the farmer than in growing wheat. The cost of raising potatoes during 1917 was nearer to a dollar than to 22 cents, but be that as it may, no matter what the cost of production may be, is any farmer, individual, merchant or company going to of his or its own free will sell potatoes to a distillery for 22 cents per bushel when he or they could by putting them on the market for human consumption receive a $1.50 per bag for them, as is the case this winter? It's an easy question to answer.

As for the remark about idle tractors owing to the high price of gasoline, this condition did prevail for a time a few years ago, but with the raise in the price of wheat, the advent of the new motor spirits onto the market, and the introduction of devices making it possible to operate successfully and more economically on kerosene—using the gasoline for starting only—this class of tractor has been rapidly coming into its own again, and I am doubtful of there having been many serviceable tractors idle during this last summer. The time has not arrived, nor will it for some while yet, when alcohol can universally compete with gasoline as a motor fuel. That time will not arrive until the prices of denatured alcohol and of gasoline or motor spirit naturally equalize on the open market. When that time comes, if it ever does, men have the data and equipment necessary for meeting the conditions and producing both the alcohol and engines suitable for using it in. Until then we can, I think, better afford to give our attention to other problems.

But, says one, you've forgotten about the sawdust we read so much about. We have got you now! Well! let's see. Ordinary wood alcohol, also called methyl alcohol, is unsuitable for use in engines. Its chemical formula is CH_3OH, sometimes written CH_4O. It is the kind of alcohol normally obtained from wood or from sawdust, although it is also possible to obtain the ethyl or "grain" alcohol from sawdust. The ethyl alcohol is the kind used in engines. Its chemical formula is C_2H_5OH, sometimes written C_2H_6O. Alexander Classen was, I believe, the first to successfully manufacture ethyl alcohol from sawdust on a practical commercial basis. By his method the raw material passed through several processes, involving some hours before the fermentation and distillery stages were reached. As to the yield of spirit, I quote from the "Canada Lumberman," August, 1903, issue:

Wood vs. Corn

"The Classen process, it is claimed, makes at least fifty gallons proof alcohol from a long ton of dry sawdust. About four and a half gallons can be made from a bushel of corn. Reduced to gallons of alcohol, one proof gallon is made from about two-ninths of a bushel, or 12.4 pounds of corn. It can also be made at no greater and probably a little less expense for the process from forty-five pounds of sawdust. . . . The Classen process is owned in the United States. . . ."

How much progress has been made in this line to date I do not know, but the same questions as regards marketing apply to this as to that of denatured ethyl alcohol made from grain or roots.

Peanut oil has, by way of experiment, been successfully used in a Diesel engine. The industry is, of course, out of the question so far as Canadian growing of the nuts is concerned. Some thirty-five years ago there were at least four peanut oil mills in the Southern States. The nuts raised there yielded 42 per cent. of oil. This was used chiefly for lubricating spinning and other light machinery. The trade, however, fell into decay. Probably the price at which oil from nuts grown in Africa and India could be obtained in America proved a handicap to the American peanut oil industry. In general I believe the nuts yield 80 to 120 bushels per acre and 38 to 50 per cent. of oil. It may be that the peanut proposition could yield a motor fuel with less expense per gallon than would be the case with the alcohol, but I do not believe the real solution of the problem lies

in this commodity either. I do believe, however, that clever chemists are working along lines which, if they do not produce a cheap and abundant liquid fuel for motors, will at least postpone indefinitely the day when we will be forced to pay alcohol prices for our motor fuel.

I know that if printed this will be read by men who want to be up-to-date and who subscribe to the POWER HOUSE in order to keep themselves so. By way of apology for submitting to these men quotations from works printed upwards of ten years ago I will add that since then the crop yields, grain and root analysis, and proportion of raw material required per gallon of alcohol produced have not noticeably changed. The chemical laws involved have not changed; and, although the prices of equipment, raw material, labor, and finished product have all increased, the relative values of each to the other, when figured on a percentage basis, have not changed so much as one might naturally suppose. Therefore, in general the data given is just as true to-day as it ever was.

CONVICTED CHEMISTRY

By R. M.

NOTHING appears to provide greater stimulus to the development and promotion of industrial and chemical science than the prosecution of a war, and this becomes additionally emphasized when the operations are on the tremendous scale of present world activities. For nearly sixty years scientific research and learning have been supported and encouraged, and institutions for its advancement have been in receipt of liberal financial endowments. In many instances community and government funds have been lavishly supplied for educational and experimental purposes. In the hope of attaining to a higher civilization men have been protesting and striving to eliminate the dominating feature of brute force that has periodically or spasmodically been manifest in the warring actions of the human race. Blinded in the belief that university investigations and scientific research have been of a constructive character—and in many respects they have—we are to-day confronted with the appalling results of the advancements of so-called civilization.

Burns has said that "man's inhumanity to man makes countless thousands mourn," but the inhumanity of the present day, particularly in relation to the prosecution of a modern war, made possible by the "advancements" of science, counts the mourners by the millions. To-day the nations of the earth stand horror-stricken before the evidence of brutalities practised by the various belligerents. The art of destruction has attained a high state of efficiency, and the scientific but odious weapons of torture, decimation and death are exemplifications of what can be achieved through a misdirected utilization of scientific learning.

In the promotion of modern civilization (so called), crimes are being committed that makes the days of savagery look like play in comparison. Poison gases, air-bombs and liquid fire are among the many achievements that vie with each other for the destruction of mankind, not as individuals but as entire battalions. Chemistry, a name that should be the key to set humanity free, stands before the bar of history convicted of the most revolting crimes that have ever been perpetrated from the very dawn of the world.

The destructive power of chemistry has created more blind men, has ruined the health of greater numbers, has maimed and destroyed the vitality of more human beings during the past three years than the curative powers of the said science can hope to prevent or safeguard during the next generation. Mars himself must surely be shocked by the perfection with which war is carried on at the present time. Instead of chemistry concentrating her efforts for the uplift of the human race the past three years has apparently demonstrated that in place of a guardian over the welfare of men she has become a trainer for this ghastly monster that threatens to completely destroy the equilibrium of the peace of the world. The present devastation should serve as a serious lesson for the development of the future, so that in some measure redemption may be possible for the loathsome acts that have resulted from chemical and other scientific achievements. This redemption can only be realized when the students of chemistry recognize their obligations to their fellows and utilize their knowledge and ability for the construction of a better and higher civilization than that which dominates the world at the present time.

READER'S QUERY REGARDING FLUE GAS ANALYSIS

IT HAS been requested that comment be made regarding a gas analysis, the results of which are as follows:

CO, carbon monoxide	10 per cent.
CO_2, carbon dioxide	25 " "
N, nitrogen	52 " "
H, hydrogen	10 " "
Hydro carbons, principally CH_4 marsh gas	3 " "

The question has arisen as to what became of the nitrogen of which ordinary air contains 79 per cent., the remaining 21 per cent. being oxygen.

The gas analysis given above is incorrect in several particulars and is impossible in actual practice when proper care is taken in the analyzing of the gas. To make this clear an example will be given showing how the proportions of the final products compare with those of the air before combustion takes place.

Let us suppose we have sufficient coal in the form of pure carbon to consume all the oxygen in 100 cubic feet of air and suppose that the final gaseous products are brought to exactly the same temperature and pressure as was the air at the beginning.

A fundamental law of physics states that equal volumes of gases of whatever kind contain equal numbers of molecules when the gases are at equal temperatures and pressures. Now one molecule of oxygen contains two atoms of oxygen and the symbol, strictly speaking, for oxygen is O_2, which shows the above fact. If carbon be burned to unite with the oxygen the resulting gas will be carbon dioxide represented in chemistry by the symbol CO_2, which symbol shows that the oxygen has taken up one atom of carbon, and the new molecule will have one atom of carbon and two atoms of oxygen in its make-up.

Since equal volumes of gases contain equal numbers of molecules at equal temperatures and pressures the resulting volume of carbon dioxide gas will be no greater than the volume of oxygen with which the carbon combined and thus the original percentages of gases will be unaltered; that is, there will be 79 per cent. nitrogen and 21 per cent. carbon dioxide in the new mixture. This is of course on the understanding that all of the carbon has been burned to carbon dioxide and that there is no water vapor or other gases to dilute the mixture.

The percentage of carbon dioxide just found is the maximum theoretical amount possible and it may be stated that such a percentage is never obtained in actual practice, usually a percentage of 14 or 15 is considered to be very good.

If now, the carbon is not all burnt to carbon dioxide another fact will present itself, and it will now be supposed that it is all burnt to carbon monoxide instead.

Carbon monoxide has the formula CO, which shows that one atom of carbon has united with one atom of oxygen thus splitting up our original oxygen molecule, O_2, into two parts. The equation representing this change may be written:

$$_2C+O_2=CO+CO \text{ or } 2CO.$$

This splitting up of the oxygen molecule affects the volume of the resulting products of combustion, for each molecule of oxygen has split up and each of the atoms of oxygen of which it was composed has united with an atom of carbon, thus doubling the number of molecules. A little reflection, bearing in mind the law above stated, will show that the volume of the gases will be doubled and the original 100 cubic feet of gas will have grown and will have the following proportions:

Nitrogen, 79 cubic feet; carbon monoxide, 42 feet, or the carbon monoxide will have a percentage of $[42\div(79+42)]\times100=34.6$ nearly.

It may be of interest to note that the total volumes of CO, CO_2 and O, in the flue gases when added together will always, if the analysis be correct, bear a certain relation to the total volume of the flue gas. One-half the volume of CO added to the volumes of CO_2 and O present, should never equal more than 21 per cent. of the total volume and this only if no hydrogen, methane or water-vapor be present, which is a condition needless to say never met with in practice.

The amount of hydrogen, 10 per cent., given in the analysis commented upon, is extremely large and it is improbable that the amount given was found.

Operators' Instruction Course

EDUCATION PAPER—VII.

IF you were installing an 8-in. steam main, 100 ft. long, carrying 100 lbs. pressure, how much expansion would you allow for?

The coefficient of expansion of a steel pipe per degree Fah. is .000,007. We will assume the initial temperature at which the pipe was installed to be 60° Fah. and the final temperature at 100 lbs. steam pressure will be 338° Fah.

The total expansion will then be $(338 - 60) \times .000{,}007 \times 100 = .1946$ ft., or 2.4 inches nearly.

* * *

How much water will a tank hold if it is 12 ft. in diameter and 10 ft. high, and if it has six 4-in. tubes running through it vertically?

The area of a circle 12 ft. in diameter is 113.09 sq. ft. The cubical contents of the tank neglecting tubes is $113.09 \times 10 = 1130.9$ cubic ft.

The area of each tube is .087 sq. ft. The volume taken up by the tubes is $.087 \times 10 \times 6 = 5.22$.

Therefore the net cubical contents is $1130.9 - 5.22 = 1125.78$ cubic feet.

* * *

What H. P. will be required to deliver 500 imp. gallons per minute against a pressure of 80 lbs. per sq. in. with a suction lift of 20 ft. and allowing for 20 per cent. friction, one lb. pressure being equal to a head of 2.31 ft.?

The equivalent head of 80 lbs. pressure per sq. in. is $80 \times 2.31 = 184.8$ ft. The total head pumped against will be $184.8 + 20 = 204.8$ ft. The weight of 500 imp. gallons of water is $500 \times 10 = 5000$ lbs. and the number of foot lbs. required to raise the water will be $5000 \times 204.8 = 1{,}204{,}000$ ft. lbs. In addition to this there is a friction load of 20 per cent. which will require 20/100 of $1{,}024{,}000 = 204{,}800$ ft. lbs. Therefore the total number of ft. lbs. will be $1{,}024{,}000 + 204{,}800 = 1{,}228{,}800$ ft. lbs.

Since one horsepower is equivalent to 33,000 ft. lbs. of work in one minute, the horsepower required is $1{,}228{,}800 \div 33{,}000 = 37.2$.

* * *

What will be the piston speed of an engine 12 in. by 17.7 in. stroke operating at 375 revs. per min.?

The piston speed will be $17.7 \times 2 \times 375 \div 12 = 1{,}106.2$ ft. per min.

* * *

What will be the speed of an engine belt if the fly wheel has a diameter of 25 ft. and the engine runs at 60 revs. per min.?

The circumference of the fly wheel is $25 \times 3.1416 = 78.54$ ft. The peripheral speed and also the speed of the engine belt will be $78.54 \times 60 = 4712.4$ ft. per min.

How much water will a duplex pump 10 in. by 12 in. deliver, running 50 strokes per minute? The pump will have to work against a pressure of 120 lbs. per sq. in. and has a friction load of 12 per cent., suction lift 8 ft. What will the H. P. be required to do the work?

The volume of water pumped will be given by the area of the plungers multiplied by the length of stroke multiplied by the number of single strokes per min. In this case the volume will be $545 \times 1 \times 50 \times 2 = 54.5$ cu. ft. or $54.5 \times 6.25 = 340.6$ imp. gallons.

The head pumped against will be $120 \times 2.31 + 8 = 285.2$ ft. The number of ft. lbs. per min. required to raise the water will be $285.2 \times 54.5 \times 62.5 = 971{,}400$ ft. lbs. The total work done including friction will be 971,400 ft. lbs. + 12 per cent. of $971{,}400 = 1{,}086{,}968$ ft. lbs. The horsepower required will be $1{,}086{,}968 \div 33{,}000 = 33$.

* * *

How should a boiler be fed?

A boiler should be fed continuously as far as possible. The water should enter at the coldest part of the boiler and the entering stream should be so directed as not to come in contact with the hot metal of the boiler.

* * *

What is meant by the term priming and what is the cause of priming or foaming as it is sometimes called?

Priming is the carrying over in the steam of water and is caused by oils or organic and vegetable substances introduced with the feedwater.

* * *

Would you fire a water-tube boiler the same as you would a fire-tube boiler?

The water-tube boiler contains considerably less water in proportion to its rated capacity than does the fire-tube boiler and thus it is considerably more sensitive to changes in firing conditions. The general laws governing efficient firing, needless to say, apply in both cases.

* * *

Why do we often see boiler fronts broken and cracked?

Boiler fronts are exposed to extreme heat conditions, having an excessively high temperature on the one side and room temperature on the other. This with the fluctuations in temperature and the unequal expansion of different parts sets up excessive local stresses in the metal and often cracks result. Another cause of cracking arises from the unequal expansion of the fronts and of the brickwork setting.

* * *

How are handholes and manholes cut in boilers?

Handholes and manholes are always elliptical in shape for two reasons. The elliptical shape permits the removal of the cover from the interior of the boiler. Also, when the manhole is situated on the circumference of the boiler the long way of the ellipse runs with the circumference and never longitudinally. This is done on account of the fact that the stresses set up in the boiler shell are twice as great circumferentially as longitudinally and the placing of the manhole in the manner indicated weakens the shell considerably less than if placed the other way.

* * *

How should the stop-valve be attached to the boiler?

The stop valve should be attached to the boiler in such a manner that no water of condensation will collect over the valve when closed or if this is impossible the steam-line should be trapped.

THERE has recently appeared on the commercial market an anti-friction alloy which is made by impregnating praphite with molten metal under hydraulic pressure. By this method the high lubricating nature of graphite is combined with the mechanical strength of the metal used, and the resulting alloy has been found to possess many desirable properties which tend to give a very promising future in the realm of mechanics. Whilst bearings made of this substance must of necessity be restricted to a limited size their manufacture forms a practical and noteworthy achievement in the great field of scientific endeavor. This substance has become known as graphalloy.

IN a paper read before the Society of Automobile Engineers by E. H. Sherbondy some interesting facts relating to the design of aeroplane engines were brought forth. The number of cubic feet of mixture which they will handle per minute is recognized as being one of the most important features of design. The mean effective pressure arrived at in the Sunbeam engines is within 15 per cent. of the theoretical maximum that is possible, while there may be some improvement secured in the future in the matter of horse-power weight efficiency by further refinement in the mechanical construction. The author believes that it is now necessary to make some change in the cycle of operation. This should be a splendid opportunity to try out super-compression and super-charging schemes of one sort or another. Possibly the two-stroke cycle engine, with its maze of new problems, stands as an opportunity, says the author.

TWIN STRAINERS

A type for every condition

The requirements for strainers are so wide and varied that no one type will meet all conditions, but from the many types of Twin Strainers, some one type can be selected that is particularly suited for any condition.

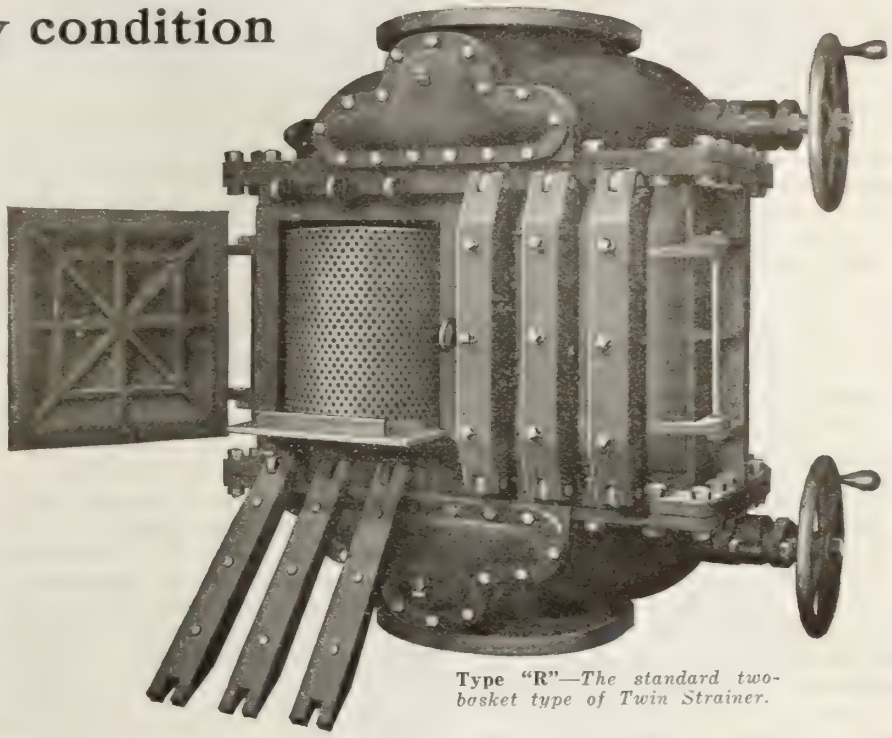
The main principle of all types of Twin Strainers is the Twin (two-in-one) feature. This feature means that when one side of the strainer is being cleaned, the other side is ready to take its place. Just move two valves—and the clean strainer replaces the dirty one—dirty because it's been doing its duty, collecting solid matter from the liquid passing through the strainer.

Twin Strainers will handle water, oil, or any other liquid, and can be installed anywhere—wherever it is most convenient.

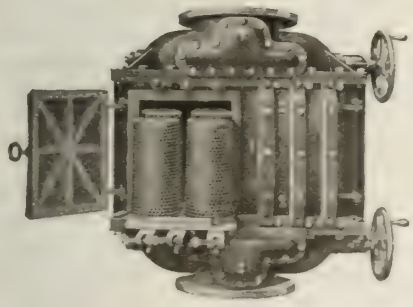
Write for Bulletin "A."

ELLIOTT COMPANY

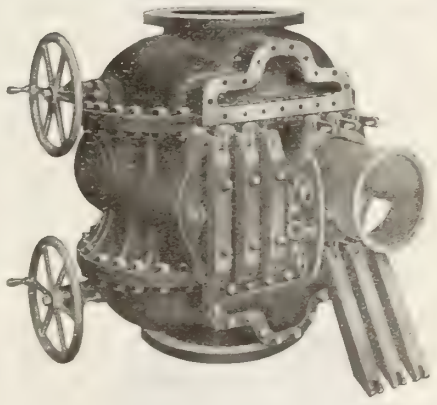
6902 Susquehanna Street
Pittsburgh, Pa.



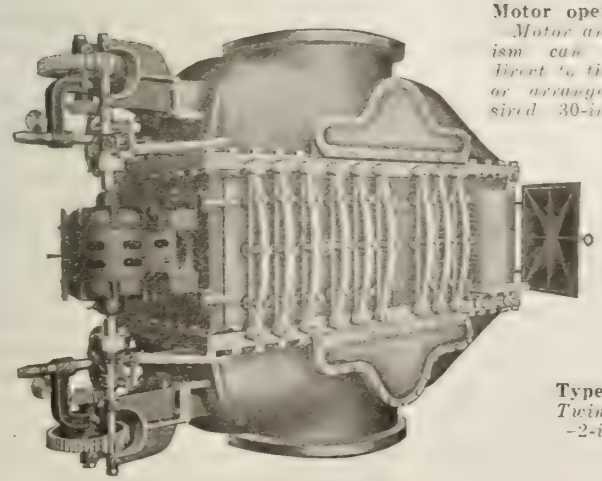
Type "R"—*The standard two-basket type of Twin Strainer.*



Type "S"—*(on the left) Suitable for use where the liquid to be strained contains large quantities of solid matter, or where it is desirable to use baskets with fine perforations.*



Type "T" — *(on the right) A special type of Twin Strainer for 150-lb. working pressure—16, 20 and 24-inch sizes.*



Motor operated Twin Strainer
Motor and operating mechanism can either be attached direct to the Strainer as shown, or arranged overhead, as desired 30-inch and larger sizes.

Type "U"—*A special type of Twin Strainer for straining oil—2-inch and smaller sizes.*

TRADE GOSSIP

Alliston, Ont.—The Town Council have decided to install a triplex plunger pump at the waterworks plant.

Windsor, Ont.—The Board of Control has awarded contracts for sludge pumps, motors, etc., for the sewage disposal works to Noble & Rich.

Summerland, B.C.—The City Council have decided to purchase a 6-inch centrifugal pump for the Trout Creek Point pumping station.

Toronto, Ont.—The A. B. Ormsby Co. have been awarded contracts for steel sash, tin-clad doors, skylights, etc., for the Bond Engineering Co's. new foundry at Ashbridge's Bay industrial district.

Strathroy, Ont.—By-law has been passed appropriating $5,000 for the purchase of a motor-driven turbine pump to be installed in waterworks system for fire protection.

Brantford, Ont.—The depleting of the Onondaga gas field to the south of Brantford is shown by the announcement that the Standard Gas Co., which had a charter for operating in this field, will apply on April 15 to have its charter cancelled. The playing out of this field cut off the supply of pure gas to this city.

The Unilectric Co. of Canada has been incorporated with head office at Edmonton, with capital stock of $25,000, to carry on business as mechanical and electrical engineers, contractors, etc. The incorporators are C. McMann, J. R. Ulery, G. B. O'Connor, G. H. Beaudry and B. Simmerman.

Matheson, Ont.—The town of Matheson is passing a by-law to provide for the borrowing of $40,000 for the purpose of building a system of waterworks and sewerage. The equipment needed comprises a concrete pump house, well, oil engine, plunger pump suction and discharge pipe, reservoir and water mains, etc. H. George Ginn is the clerk of Matheson.

To Make Steel.—Canada Western Steel Co., Calgary, are putting in an open hearth plant at Redcliffe, Alta. This is a unit plant of 220 tons capacity and is being built so that other units may be added in order to make a battery. They will make all grades of open hearth steel. It is expected the plant will be ready for operation in July or August. George A. MacKenzie is the managing director.

Chatham, Ont.—Use of chemicals in increased quantities in the treatment of the civic water supply is recommended in a letter received by the water board from Engineer Willis Chipman, of Toronto, following an investigation made into local conditions recently. It is stated that the quantity of sulphate of alumina could safely be doubled and an increase of 25 per cent. made in hypochlorite. Tests of the city water show that it contains bacteria of intestinal origin.

Niagara Falls, Ont.—A deposit of coal has been found by the engineers of the Hydro constructing the Chippewa-Queenston Hydro Power Canal. Excavations of 170 feet are necessary to construct the canal, and on Saturday the coal deposit was struck at a depth of about 150 feet, near the Whirlpool. The coal is of rough variety, being what is known as rock coal, but it is burnable, and if there are any quantities of it there this may prove a rich find for the Hydro and the province generally.

Tender for Power Plant Equipment.—Tenders for the following equipment for the Water Supply Department, Queensland, Australia, will be received until July 15, 1918:—1. Supply, delivery and erection of complete boiler-house equipment for an electric power-house in connection with the Inkerman irrigation area, near Townsville, North Queensland. 2. Supply, delivery and erection of steam-driven turbo-alternators to be installed for the Inkerman irrigation area, near Townsville, North Queensland. Tenders to be addressed to the Under Secretary, the Treasury, Brisbane, Queensland.

Montreal, Que.—W. C. Hawkins, president of the Southern Canada Power Co. was in the city recently in conference with the other officials and engineers of the company in connection with the completion of the plans for the company's hydro-electric development at Drummondville, Que. This development will have an ultimate capacity of 17,000 to 20,000 h.p., but the electrical equipment to be installed now will be about 10,000 h.p., the remaining equipment to be installed as the demand warrants. The installation will be completed within a year or 15 months.

Coal Prices Firm.—While there has been a reduction in United States points on coal during the past few days, values in Canada for the most part remain the same as during the past winter. Toronto dealers are asking $9.75 and $10 for egg and nut. They claim that the freight and lake rates have been increased and that it is costing them more to take care of the business. Under the new regulations a person who burns over six tons of coal during a winter comes under the restrictions. Such a person can get seventy per cent. of the amount he requires. That means that a person who burned ten tons could purchase seven until such time as the order is rescinded by the provincial fuel controller.

Comparative Tests of Six Sizes of Illinois Coal on a Milkado Locomotive.—Bulletin No. 101 contains data covering a series of tests to determine the value of different sizes of coal as conducted by the Engineering Experiment Station of the University of Illinois under a co-operative agreement with the International Railway Fuel Association and the U.S. Bureau of Mines. A Mikado locomotive weighing 142 tons belonging to the B. & O. R. R. was used, the tests being made in the locomotive laboratory at Urbana. The results are published in above bulletin No. 101 by E. C. Schmidt, J. M. Snodgrass, and O. S. Beyer, Jr. Copies may be had without charge by addressing the Engineering Experiment Station, Urbana, Illinois.

To Make Fuel.—The Dominion Government has fallen in with the recommendation of the Advisory Council for Scientific and Industrial Research for the manufacture of a domestic fuel from Saskatchewan's supply of lignite. A sum of $400,000 has been provided for this purpose. In this undertaking the Dominion Government is acting in co-operation with the governments of the provinces of Saskatchewan and Manitoba. The council has received a request from the Ontario Government asking that that R. A. Ross, C.E., one of the members of the council, be appointed to act with Arthur Cole, C.E., as a committee to take immediate steps for the development of the peat bogs of Ontario, and the production from them of a merchantable fuel. The Research Council has concurred in these appointments and the investigation will be proceeded with.

Ottawa.—Sealed tenders will be received until noon, April 23, 1918, for electric conduit and fittings required in the reconstruction of the Parliament Buildings, Ottawa. All tenders to be based on the supplying and delivering on the site of the quantities of the schedule of material for electric conduit and fittings, in strict conformity with the specifications and the samples submitted and to the satisfaction of the architects. Deliveries to commence so far as possible immediately after the signing of the contract and to continue as directed in such quantities as to ensure complete delivery by June 1, 1918. The schedule of material, specification and any other information required can be obtained at the office of the P. Lyall and Sons Construction Company, Limited, Ottawa; John A. Pearson, architect; J. O. Marchand, associate, Centre Block, Parliament Hill, Ottawa.

Garbage Fuel.—"When the coal shortage was most acute and manufactured fuel was being advocated," says the Hamilton "Times," a good deal was said about the success of a garbage fuel plant in Colorado City, which was said to be a great success. To-day the "Times" received a letter from E. F. McGowan, of Denver, Col., president of the Minequa Coal Company, who writes as one of those who went into the garbage fuel project. Mr. McGowan says he has read in the "Times," the report of the proceedings in Hamilton, and the account of the success of the plant referred to. He adds: "We have spent over $51,000 on this plant. It is first class in every way, as near automatic as possible. We have shut down everything and have boarded up the windows. A little later we are going to sell the machinery for what we can get for it." He declares that the project is not a success and advises any city which contemplates going into it to go and see the plant or get in touch with him.

Kingston Civic Plants.—The Public Utilities Commission at the present time are installing a 5,000,000 gallon De

Laval motor-driven pump at the local water works pump house. This will give the commission two independent sources of supply—5,000,000 gallons electrically, and 7,000,000 gallons in the steam pumps, there being one Inglis engine of 4,000,000 gallon capacity and one Killey engine of 3,000,000 gallons. The power for the new electric pump will be furnished by an independent three phase feeder line over a separate line of poles running from the main power house, which is used jointly with the Hydro-Electric Power Commission as their new sub-station. In addition to the alterations at the pump house the commission have purchased a 300 k.w. and one 150 k.w. motor generator set to operate the local street railway; these machines to replace the present 350 k.w. engine-driven generator now in operation. The main power house at the corner of King and Queen streets has been completely overhauled. Transformers capable of looking after 1,000 h.p. have already been installed and in addition to the above a supply of power is furnished by the Gananoque Electric Light & Water Supply Company at Kingston Mills, over a 13,200 volt transmission line. The local commission are considering extensive alterations to the different plants during the present year, among them being the erection of a 300,000 cub. ft. gas holder recently purchased from the Davis & Farnum Manufacturing Co., Waltham, Mass.

CATALOGUES

New Line of Torches.—The Canadian Welding Works, Montreal, P.Q., are placing a new line of cutting and welding torches on the market. The torches are of special design and incorporate a number of special features that increase the efficiency of the appliance.

Cochrane Multiport Valves, a new bulletin issued by the Harrison Safety Boiler Works, Philadelphia, Pa., contains information covering the principal features of the Cochrane multiport valves. Copies may be obtained on application from the exclusive Canadian agents, Canadian Allis-Chalmers, Ltd., Toronto.

The Smooth-On Mfg. Co., Jersey City, N.J., have issued a sixteen-page circular containing extracts from Smooth-On instruction book No. 16. One particular feature of this circular is that it contains the standard sizes of Smooth-On coated corrugated gaskets for flanged pipes from 2-inch up to 26-inch. Copies of the booklet will be gladly sent on application.

The Darling Digest is the title of a new house organ to be issued monthly by Darling Bros., Ltd., Montreal. The first March edition has been distributed. It is the intention of the company to make the publication interesting, helpful and instructive, and to give each month information of a reliable nature regarding their products and doings and to bring their customers and friends into closer personal touch with the organization. The bulletin will also from time to time contain interesting technical talks on the manipulation of heating systems, steam specialties, pumps and products generally.

New Safety Switch Bulletin.—Safety auto-lock switches are described and illustrated in some detail in special publication No. 1585-A, just issued by the Krantz Mfg. Co., Inc., of Brooklyn, N.Y. These switches are designed for use on circuits wherever the ordinary knife switch may be applied. They are especially designed for safety, it being absolutely impossible to touch the live parts regardless of the position of the switch or of the door. They are particularly adapted for use in steel mills, factories, mines and other similar locations where men are employed who have no practical knowledge of electricity.

Electrical Heating Publication.—Of interest to everybody connected with the heating of baking, drying, and japanning ovens is a reprint just issued by the Westinghouse Electric and Mfg. Co., of East Pittsburgh, Pa. This includes an article, "Electrically Heated Japanning Ovens," by C. F. Hirshfield, reprinted from the N.E.L.A. Bulletin, and "Heat Calculation for Baking and Drying Ovens," by W. S. Scott, reprinted from the "Electric Journal." Thus there are grouped under a single cover an article giving general considerations in favor of electrical heating for this purpose and an article giving the detailed method of calculation for the amount of heat required to raise the temperature of the work, of the supporting and carrying parts, such as trucks, and of the ventilating air. How to compute the losses from the external surface of the oven and the heat required to raise the temperature of the oven walls, etc., are also given. This publication should be of much value to central station solicitors, who are endeavoring to interest their customers in the electrical heating of ovens, as well as to present and prospective users of such equipment. Copies will be furnished on application to any Westinghouse Electric branch office for Reprint 66.

SOME NOTES ON THE HISTORY OF ARTIFICIAL FLIGHT

While the history and development of the aeroplane and the dirigible may be said to be confined almost entirely to the present century, there were a few venturesome pioneers in the past ages who speculated with optimism upon the possibility of man's conquering the realms of the air.

Aviation

Aeronautics is divisible into two main branches—aerostatics, dealing properly with machines which are lighter than air, and aviation, dealing with the problem of artificial flight by means of flying machines, which, like birds, are heavier than air, and also with attempts of human beings to fly by the aid of wings fitted to their limbs.

As might be expected the fitting of artificial wings, being the most natural means of locomotion to suggest itself, would first appeal to the imaginations of men, and so Greek mythology and Egyptian bas-reliefs

Thrift is the Surest Rudder in This Time of National Peril

Save Fuel

Our Book, "Steam Condensation," tells how this can be accomplished.

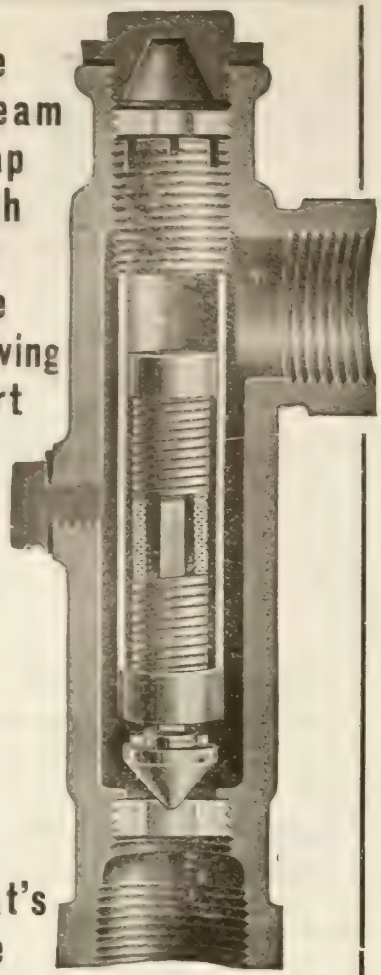
The Steam Trap with but One Moving Part



That's the

SARCO

You can replace bucket or float non-return traps with the Sarco. When you do, you throw out of service trouble makers with joints, floats, levers, toggles, etc., etc., and replace them with a steam trap with but one moving part, operated hydraulically and absolutely reliable. You save in first cost, save in repair cost and save in worry cost.

Send for Special List No. J-6

both suggest this means of locomotion.

John Wilkins, one of the founders of the Royal Society, discussed the possibility of flying to the moon and cites several myths or fables, to him true, of men who had succeeded in flying by means of wings. One of these, a monk, living in Edward the Confessor's time, was said to have flown a distance of about a furlong.

Francis Bacon likewise in his Natural History discussed the possibilities of artificial flight, but in a manner obscure and somewhat confused.

Leonardi Da Vinci

One of the most versatile men of any age, Leonardi Da Vinci, who was painter, sculptor, architect, musician, mechanician, engineer and philosopher, devoted some of his time and inexhaustible genius to the study of artificial flight. He excelled in all of these and in engineering and scientific subjects was in many instances a pioneer.

For one living in the fifteenth century his knowledge of science in general was remarkably complete and accurate, and in one of his sketches he pictures a machine so closely approaching to the modern aeroplane in design that had it been fitted with the proper motive power it might conceivably have flown.

The Flight of Birds

The impossibility of man's flying by means of wings and unaided by any external motive power was first clearly pointed out by G. A. Borelli in 1680. By means of an examination of the flight muscles of birds and calculations as to their enormous power he clearly pointed out the impossibility of man's being able to suspend himself in the air by means of his muscular strength alone.

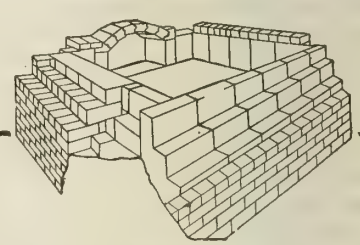
Many attempts have been made to devise means of flight patterned after the wings of birds and provided with motive power for effecting the flapping of the wing members, and while the principles underlying bird flight are well understood and while excellent models have been made which have flown considerable distances, no device sufficiently large enough to sustain a man has as yet been constructed, possibly because of the many disadvantages and constructional difficulties inherent in this type of machine.

Dr. Johnson and Aeronautics

The great English lexicographer, Dr. Johnson, was perhaps the first to state with accuracy the principle involved in any successful effort with "heavier-than-air" machines. How it happened that he, who had but a casual acquaintance with the science of his time, directed his attention to this matter, it is now impossible to say.

In 1759, to raise money for payment of charges consequent upon the death of his mother, he wrote "Rasselas, Prince of Abyssinia," a remarkable book telling of a quest for happiness. The story relates that before starting on his travels with this object, the prince, amongst other devices to relieve ennui, had consorted with men of learning and skilled exponents of various arts; amongst these, a mechanical genius, referred to as the "artist," who, to provide amusement for his patron, suggested an attempt at flight, and in discussing the matter says: "He that can swim needs not despair to fly; to swim is to fly in a grosser fluid, and to fly is to swim in a subtler.' Then follows this enunciation of principles: "We are only to proportion our power of resistance to the different density of matter through which we are to pass. You will be necessarily upborne by the air, if you can renew any impulse upon it faster than the air can recede from the pressure." This is a remarkable statement having regard to the state of knowledge at the time—159 years since. It correctly defines the principle underlying "heavier-than-air" aviation.

Dr. Johnson's was a mind extraordinarily active, and not to be deterred from addressing himself to a strange subject by its strangeness merely, so that no great surprise need be felt that he should consider this, but only that he should have made so illuminating a pronouncement with respect to a branch of study alien to his usual pursuits. By a Newton it would have been stated with more of mathematical precision and effect, but not more truly. It is not improbable that Johnson, mingling with the intellectuals of his time, got the idea, expressed so well, from one of these, but there is no evidence of this, and we need not question but that his naturally vigorous intellect was well able to go straight to the root of such a matter, even though it might be on ground unfamiliar to him.



Gates Boiler Furnace

Patented 1916

Will last three times as long as ordinary good grade Fire Brick. These blocks are inter-locking, and made so that any handy man or fireman can renew them without disturbing any of the other brick work.

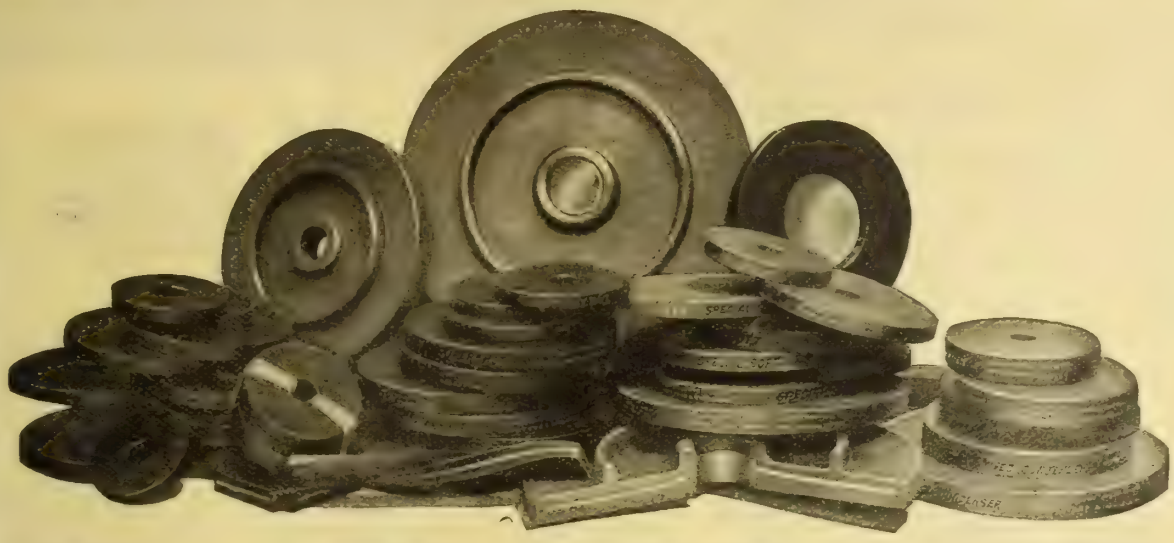
THE CANADIAN FAIRBANKS-MORSE COMPANY, LIMITED



STANDARD SUPER-HOT SPECIAL SOFT RED CONDENSER

Rub-Steel Valves

"THE VALVE WITH A BACKBONE"

WHAT IS IT? The Rub-Steel Valve is a valve made by a combination of rubber and steel.

THE CONSTRUCTION The construction consists of a plate of high grade steel placed in the center of the valve with a specially tough and lasting rubber composition on each side and edge, attached securely and lastingly to the metal by the Elchemo process, which chemically unites the rubber and steel.

THE PURPOSE The steel plate gives such strength to the valve that the highest pressure cannot warp, twist or in any way get it out of shape, while the rubber surfaces afford the proper seating qualities. **"Better than Metal Because of the Rubber—Better than Rubber Because of the Metal."**

WHAT IT ACCOMPLISHES It gives the valve a rigidity of form. It keeps the surface of the valve in its normal true position and insures a better seating quality. It prevents the high pressure from forcing the valve through the grating. It prevents the rubber from breaking up and the pieces causing trouble. It holds the surface of the valve in shape, so that when one side becomes worn the valve can be reversed without dressing. It is thinner and therefore gives greater efficiency to the pump. It permits the use of a softer valve for hot water, thus securing a better seat on worn or uneven "grids." It ensures an even distribution of the pressure, preventing "dishing" and the consequent cutting of the valve.

WHY YOU WANT IT **Because** its ultimate cost is less than that of ordinary type valves. **Because** it will last longer than other valves. **Because** it saves time and annoyance of replacement. **Because** its construction at once appeals to you as practical and sensible.

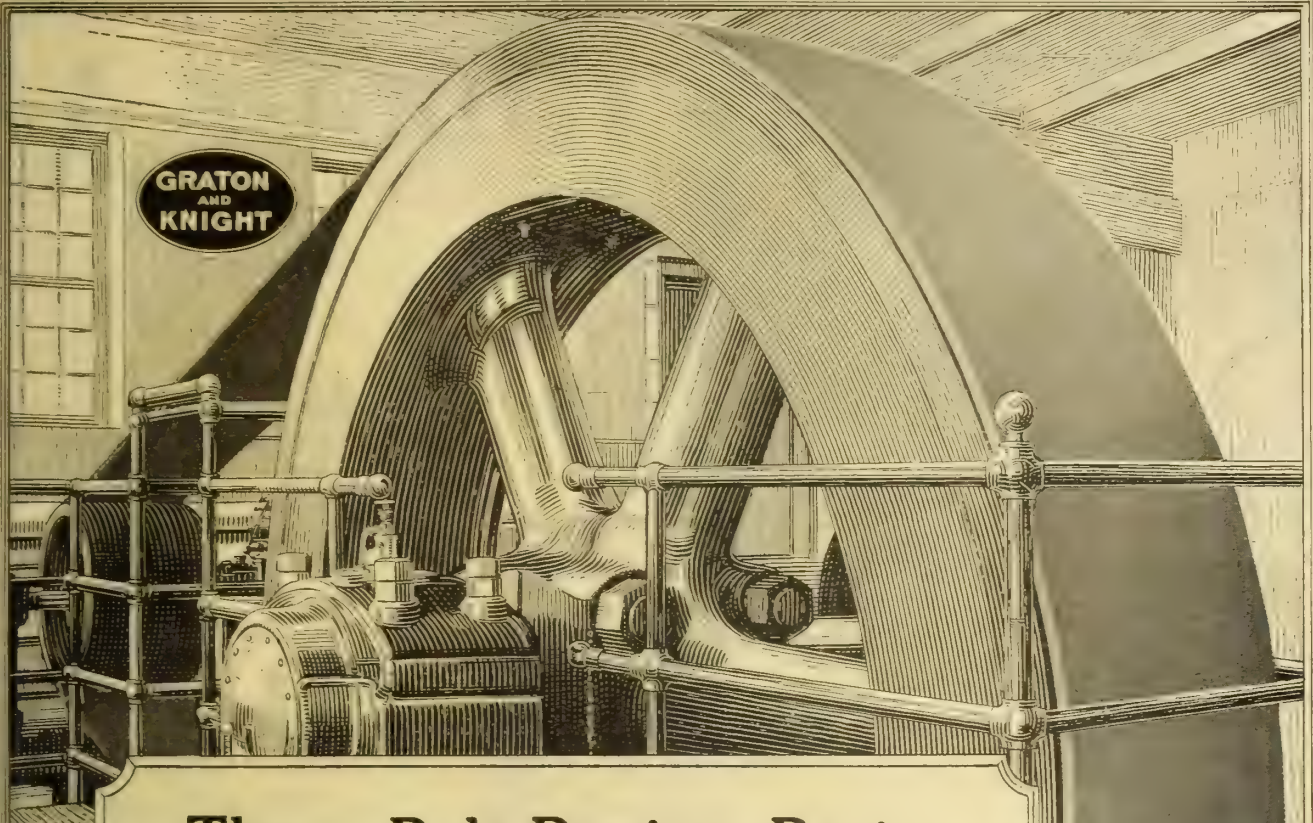
CANADA'S REPAIR PARTS STORE FOR MACHINERY OF EVERY DESCRIPTION



Three Belt-Buying Basics

LEATHER

Of all belting materials, leather is pre-eminent for long wear under hard usage; for frictional grip on pulleys; for standing the strain of main drives and the side-slap of shifters; for ease of repair and splicing; for minimum power-leakage; for that **light-weight** pliability, firmness, and elasticity which good belting must possess.

TANNAGE

Belting leather requires a special tannage. We tan nearly 300,000 hides a year for belting use, giving you two great advantages: All our belts are of leather of the best possible quality for belting requirements. Our enormous stock of hides enables us to maintain a uniformity throughout our product that can be assured in no other way.

STANDARDIZATION

Power transmission needs fall into comparatively few classes For each one there is a Graton & Knight Standardized Belt. That means a belt which is scientifically built for exactly the class of duty to be performed. It is kept uniform. It pays us to make it standard for quality, because it pays mill-owners to make it standard for use.

Many of the best belted plants ask us to specify the belting for every pulley. Try the plan yourself. Then, when buying call for "Graton & Knight——Brand or equal." This won't commit you to buying our belts. It will put your buying on the one basic consideration—**the work to be done.**

Write for information about Standardization as applied to Belting.

Alberger
Multi-Head Heater

Keeps water hot to supply all demands. It heats the water just as fast as it can be drawn.

The Multi-Head feature takes care of unequal expansion of hot and cold tubes—no trouble whatever from expansion strains.

The Alberger Heater will give you perfect service for years and the most economical. Made in horizontal and vertical types for all services.

Alberger Tubes **transmit 50% more heat** than plain tubes. Alberger tubes are small and corrugated: **Small** because usage shows that small tubes transmit a much greater quantity of heat per square foot of heating surface than large tubes; **Corrugated** because usage shows that corrugated tubes transmit over 50% more heat than plain tubes of the same size.

Alberger Tubes are pure copper, for the reason that pure copper tubes, unlike brass, are not subject to segregation of materials nor will they split under temperature changes.

Write now for Catalog.

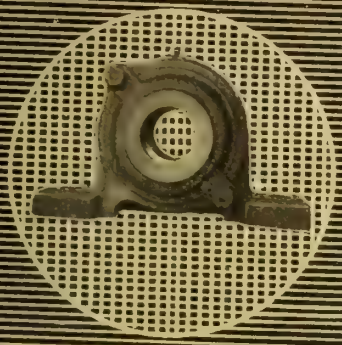
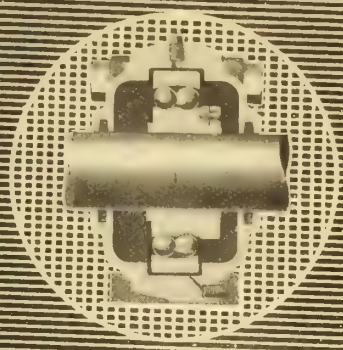
SKF
BALL BEARINGS AND RIGID PILLOW BLOCKS



Full View of Rigid Pillow Block



Sectional View of Rigid Pillow Block

They Insure

1. Saving in Power. 2. Saving in Maintenance.
3. Saving in Lubrication. 4. Saving in Equipment.

How to Measure Transmission Losses

ELECTRICALLY EQUIPPED PLANT

First: Throw the belt off the motor driving the shaft to be tested and take proper reading for input to drive motor only.

Second: Put the belt back on the motor pulley and shift all belts on the main line to the idler pulleys on the counters. Take power reading. The difference between these two readings will show the net line shaft transmission loss.

STEAM PLANT

First: Ease the belt off the fly wheel or pulley of the engine, indicate the engine.

Second: Put the main driving belt back and run line shafting at normal speed with all belts driving loose pulleys only, indicate the engine. The difference between the indicated readings with the main belt off and on will show the net line shaft transmission loss.

It will then be a simple matter to figure out in dollars and cents the amount wasted annually in the friction loss of plain bearings, and it will be easy to determine if it is worth while to save 50% of this waste by the application of SKF Ball Bearing Hangers or Rigid Pillow Blocks.

THE DUNHAM RADIATOR TRAP

How to Heat Buildings Quicker, Easier and More Economically

The Dunham Radiator Trap is a big coal saver because it gets every last bit of heat out of the coal. Besides it gives *you* the following advantages:—

It prohibits steam waste. Jet water at vacuum pump is not required.

Steam circulates easily through radiators and coils because air is eliminated.

You'd like to do that for the owner of your building, wouldn't you? Every engineer would.

All right! Here's the way to do it. Recommend that the radiators be equipped with Dunham Radiator Traps. Many of the largest buildings in Canada are so equipped. These buildings are being heated at a surprisingly low fuel cost because less fuel is required.

Let us tell you more about The Dunham Radiator Traps. Write us.

The function of lubricating oil is to give the greatest ease of motion to all parts of the engine, so that every possible atom of power may be transmitted to the machines. An oil that will do this will have effect on other divisions. Ease of operation would mean elimination of friction, no wear on the bearings, less oiling. Pure oil would be a decided labor-saving, cost-reducing, efficiency-promoting factor in the engine room. A great many Canadian manufacturers have pronounced our "Non-Corrosive Cylinder Oil" pure. We, who know its construction, pronounce it pure. Get in touch with us.

"VULCABESTON" RED FIBRE STEAM STEEL SHEET PACKING

Buy "Annual" Economy in Packing

Per-year economy in packing, as contrasted with per-pound cheapness, saves you the loss of time and efficiency caused by inferior grades.

The long-fibre asbestos used as the base of VULCABESTON, is treated with a scientific composition that gives it:

—Efficiency in preventing leakage;
—Durability under hardest usage;
—Adaptability to every packing purpose;
—Resistance to all climatic conditions;
—Power to conform automatically to contracting or expanding metal.

These features of VULCABESTON establish it as the most reliable and economical packing you can buy.

JOHNS-MANVILLE SERVICE
COVERS THE CONTINENT

JOHNS-MANVILLE

Behind the Power that Turns the Wheels of Your Life

YOUR food, your clothing, your equipment for life's work, come from the collective efforts of thousands of manufacturing plants, which in the struggle to meet your demands, compete in quality, in price and in service.

To do this, these manufacturers must operate their establishments at highest efficiency—must protect their plants against countless costly leaks such as waste heat, friction, wear and tear, and breakdowns.

Many American manufacturers rely on Johns-Manville maintenance materials to check these losses. For example, they improve the efficiency of pumps and engines by packing them with Johns-Manville Sea Rings, the packing that reduces friction to a minimum. The brick arches over the blazing boiler fires are protected from the flame's white heat by Johns-Manville Refractory Cements. Again, the valuable heat transferred through pipes, ducts and flues is conserved by Insulations made from Johns-Manville Asbestos and Magnesia. And in hundreds of other instances, Johns-Manville materials are employed to reach you with a better product at the lowest cost.

So that of all the ways—some direct, some devious—by which Johns-Manville serves the public, none is more important than this function of maintenance, this power economy at the very heart-center of industry.

"John Crane" Flexible Metallic Packing is without a doubt the present

SENSATION

of the packing world.

It is "just what every engineer wants," and that is why we are receiving such an abundance of enthusiastic repeat orders from all over the world.

"John Crane" is made of sheet babbitt spirally and evenly wound from the center outward. It is NOT a mixture of babbitt and fabric. It is ALL babbitt.

It makes an ideal packing for the same reasons that babbitt makes a good bearing. It is the only

Flexible Metallic Packing

that is based on scientific and practical principles. You can cut it with a knife just like fabric. You can bend it like fabric. You can form it to fit the box BETTER than fabric. And more important still, it resists EVERYTHING—steam, gas, oil, air, ammonia, water, etc. You needn't carry a dozen different kinds of packing in stock. Simply keep some "John Crane" handy and if the rod is a good one the packing won't wear out for years. We haven't room in this ad. to tell you about our many installations, but will gladly tell you all about "John Crane" on request.

You certainly want the best packing obtainable, and for that reason you should get in touch with us at once. Ask for Bulletin No. 1.

DART UNIONS

Defy Time, Pressure, Corrosion Vibration and Expansion

Bronze to Bronze at the Joint

When the BRONZE FACES of Dart Unions are drawn together you have a joint that is practically everlasting in its efficiency.

The BRONZE FACES of Dart Unions never deteriorate, and their heavy iron parts is a guarantee against stretching or pulling apart.

Absolutely no leaks—no upkeep cost—no replacement cost—easily connected.

The ball-shaped seat allows for an easily made and perfectly tight connection, whether pipes are in or out of alignment.

GET THEM FROM YOUR JOBBER.

All Down the Line—

You'll find sizes and types of

Jefferson Unions

for every union need — why not standardize them and put an end to pipe line troubles throughout your plant?

The Jefferson feature of forcing the brass seat ring into a recess just back from the runway and contents of the pipe makes it corrosion-proof and at the same time much more durable than a bronze or brass seated union handled in any other way. Then the weight of a Jefferson is greater than any other union of similar class—another logical "reason why" they are most successful.

If your jobber can't supply Jeffersons, a line direct to us will bring you the name of our nearest dealer and the Jefferson Book "Unions" — a treatise on pipe line connections whch you'll enjoy reading.

Jefferson Union Features

Ground ball brass-to-iron or iron-to-iron joint ground with mate and never separated.

Sloping shoulder and large play in the ball end, which is of assistance in connecting piping out of line.

Standard pipe threads tapered to fit the pipe. Coarse nut threads for quick adjustment.

Heaviest of its class made and sold at reasonable prices.

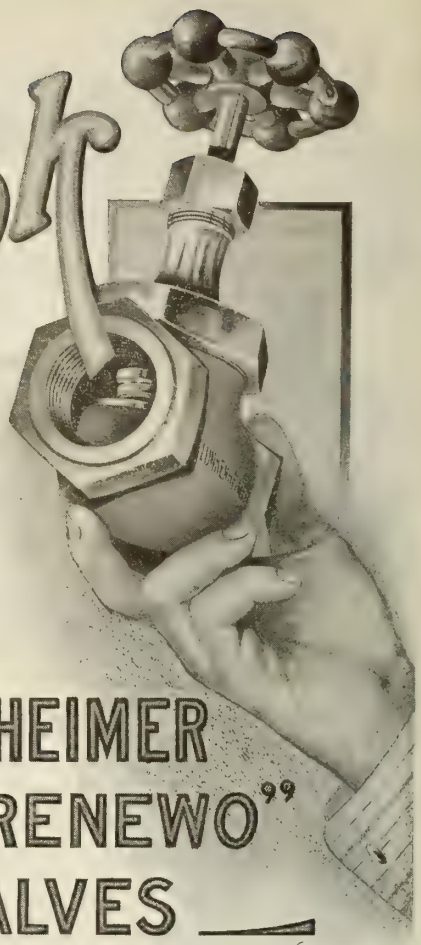
Look



and satisfy yourself of the many advantageous features embodied in

LUNKENHEIMER "FERRENEWO" VALVES

Note the *seat ring* and *disc*,—both of which are made of Lunkenheimer "Valve-nickel," a material having exceptional wearing qualities; the regrindable seating surfaces; the renewability of all parts, including the *seat ring* and *disc;* the full areas through the body; union bonnet; special composition stem, which insures long life to the stem threads; deep stuffing box, etc. These features combined with Lunkenheimer "quality" materials and workmanship make the "FERRENEWO" *the* valve of exceptional merit.

Globe, Angle and Cross, and Horizontal and Angle Check Patterns, for working steam pressures up to 150 pounds.

Your local dealer can furnish them; if not, write us. Write for descriptive Booklet No. 567-DJ.

MUELLER

Globe and Angle Valves

BUILT from actual, practical experience. Made of the famous *MUELLER* steam metal and fully guaranteed against all defects in design and construction. Not a Valve, but *the* Valve.

¶ *MUELLER* globe and angle Valves can be repacked under pressure. The disc is so designed as to adjust itself to any position and still receive the thrust of the spindle on the center line; thus preventing any distortion to the seat or diaphragm. The pipe threads are full length, and are tapered to conform to I. P. Threads, insuring perfect joints.

¶ Full sized and unobstructed passages guarantee full service. The large Hexagons allow an excellent wrench grip and our design puts the strain where it belongs, so that there is no danger of distorting either the body or the bonnet. Furnished with enameled, Malleable iron wheel handles. Every *MUELLER* Valve tested to beyond unusual service conditions. Write for prices.

MUELLER gate and check valves, steam cocks, etc. rank highest in every branch of exacting service.

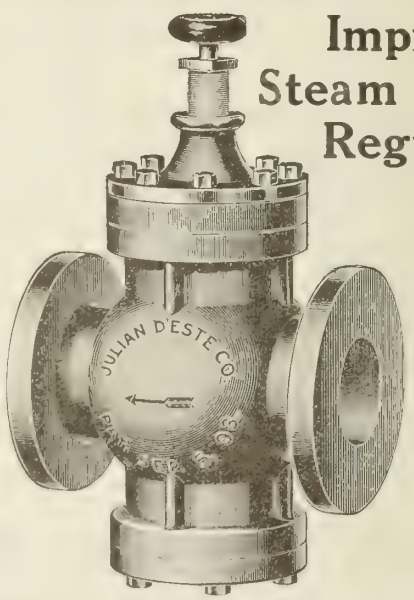
CURTIS Engineering Specialties

Improved Steam Pressure Regulator



For Universal Application to all the varied and various conditions under which a reduced pressure of steam, water or other fluid is required, this Regulator (see illustration) has no equal. It is compact and self-contained, without levers, weights or projections.

No glands or packing; no drip or leak of steam or water. Suitable for any boiler pressure; made entirely of metal; is a lock valve, very simple and sensitive.

The universality of use of this Regulator is one of its best features, but it is in Steam Heating that its use is most common and obvious. Send for leaflet fully descriptive of this Regulator (contains price list) to the manufacturers.

Canadian Association of Stationary Engineers

Incorporated May, 1887 Incorporated at Ottawa, June, 1917

An organization having as its aims and objects:—

To promote the knowledge of its members in the art and science of Steam Engineering.

The dissemination of information beneficial to the members of the association in the discharge of their calling.

To further and protect the interests of competent engineers, and receive such as members of this organization.

To secure, through proper legislation, the greatest security in operation of steam plants.

To assist unemployed members to secure positions.

To maintain freedom of action between employer and employee.

The members of the Association subscribe to the above in the full belief that ability and knowledge of one's profession are necessary to insure the highest degree of success.

Labor Study Energy

These three essentials have been responsible for the success of the world's greatest men. They are no less essential for yours. We cannot all become great, but this fact does not lessen the necessity for the exercise of these essentials in our individual occupations. Cool, calm, calculating judgment characterizes the successful power house operator of to-day. The demands on the engineer of to-day are many, and the obstacles in his path are great. To assist in the overcoming of these and help the accomplishment of great works, material, moral and educational, is the desire of all our members.

The benefits accruing from association with members of his fraternity, the opportunity to benefit by their experience, and the inspiration to greater effort by reason of their success render membership in this association indispensable to all progressive engineers.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

J. H. HALE, General Secretary, C.A.S.E.

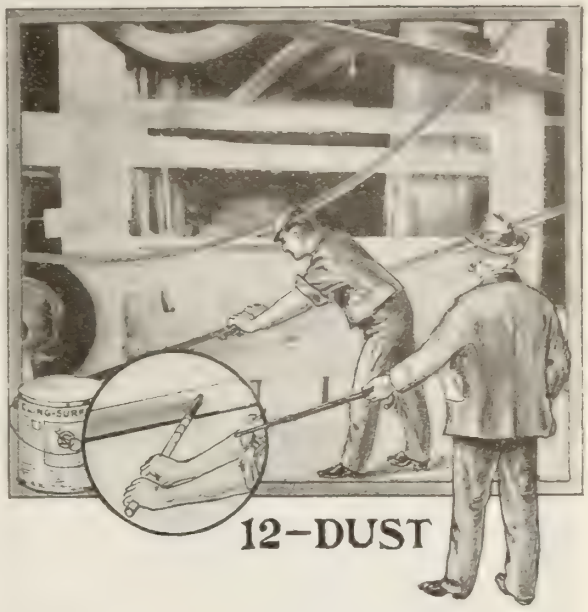
ALEXANDRIA, ONTARIO



Dont Claim Exemption

—because the air is filled with dust,
—because this dust settles on the belts,
—because it makes a belt dressing "ball up"
are no reasons at all why your belts can't have the benefit of

CLING-SURFACE Belt Preservative

Just wipe the dust off first.

Then with the swab (as shown) treat the face of the belts **a little at a time.**

Your belts will absorb CLING-SURFACE very quickly, leaving a clean, **not sticky,** surface.

It will be smooth, velvety, and will not slip.

Nor will it hold the dust.

Your drives will last longer, do more work, cause no trouble, and can be run easy or slack under full loads.

They will never again have static electricity.

* * *

Results like these PAY.

Are you willing to try this treatment if such trial **costs you nothing?**

Then write to-day for the 25-pound can we have waiting for you.

Use it sixty days.

If you're satisfied, pay us for it. If not, we will take back what you have left, charge you nothing for what you've used, and pay the freight both ways.

ALL CHEERFULLY—no hard feelings!

Remember, use CLING-SURFACE and you won't need belt dressings.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914 With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID, Minister of Public Works and Highways

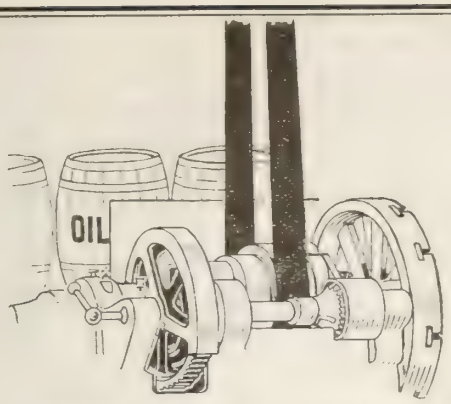
Plan of "Bennis" Coal Bunker with Elevator feeding a "Bennis" Stoker

Plants similar to the above have been installed in many of the new National Factories to ensure maximum output and rapid and efficient handling with the minimum of labour. "Bennis" Conveyors and Elevators are indispensable for the cheap and efficient transport of material in bulk. Schemes prepared to any requirements.

Write to-day for descriptive literature.

ED. BENNIS & CO., LTD.

Little Hulton, Bolton; 28 Victoria Street, S.W. London, Eng.



Scandinavia Belting

Is a Good Belt For Oily Places

Please do not understand from this that this belt or any other will give good service if it is constantly reeking with oil. Any oily or greasy belt will slip, and a slipping belt will burn and crack.

What we mean is that the action of the oil does not have a bad influence on the fabric itself to any extent. To get good service, if the belt is continually being subjected to oil, keep the oil cleaned from the pulley side of the belt and apply "Agrippa," a belt adhesive, to overcome the tendency of an oily belt to slip.

"Scandinavia" is one of the belts on which an adhesive may successfully be used, and this is not true of all belts, as the adhesive often opens up the joints or plies. "Scandinavia" has neither joints nor plies.

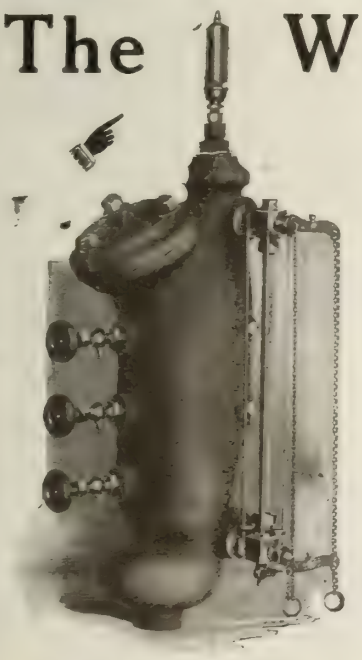
If you have any belt drives such as described above try this belting and if you follow the above suggestions you will be surprised.

Federal Engineering Co., Limited

172 John Street - - - Toronto, Ont.

Note:-Do not use "bar" or "stick" dressings on textile belts

The Whistle Instantly Blows!



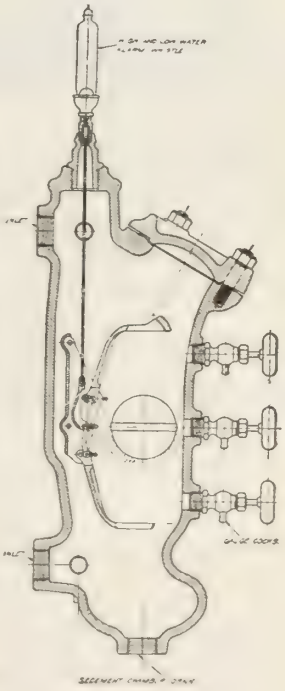
Exterior

When the water in your boilers rises above or falls below its proper level you should know it instantly.
If you are depending upon a gauge glass you are taking risks. Rid yourself of all worry and care of boiler explosion in your steam plant by installing

THE ANDERSON Safety Water Column

The "Anderson" sounds the high and low water alarm plainly, unfailingly, and unceasingly. With it you know whether the water is RIGHT or not.

Extremely simple in design, as will be seen by accompanying engravings. The operating mechanism is assembled as a single unit in a removable hanger frame suspended from bronze pivots. The rise or fall of an unattached seamless Lake Superior copper high pressure float strikes against this mechanism, which in turn holds the small steam whistle valve open as long as the water level remains above or below normal.



Cross Section

The **Anderson Safety Water Column** is equally adapted for any old or new boiler—any make, size or description. Our illustrated catalog is worth sending for. Write now.

The V. D. Anderson Company

1935 West 96th St., - Cleveland, Ohio

CRUSHER WILL BE PLACED AT LIGHT PLANT

Order is Sent to Columbus Company To Rush Machine.

FACTORIES ARE PROMISED RELIEF

To facilitate the handling of coal into the conveyor at the plant of The Springfield Light, Heat and Power company a coal crusher with a capacity of fifty tons an hour will be installed at once. An order was placed by the light company with The Jeffrey Manufacturing company of Columbus Friday morning for the shipment of the crusher.

The crusher has a capacity of fifty tons of coal an hour which is more than sufficient to meet the needs of the light company in providing power, light and heat for the manufacturers and citizens generally.

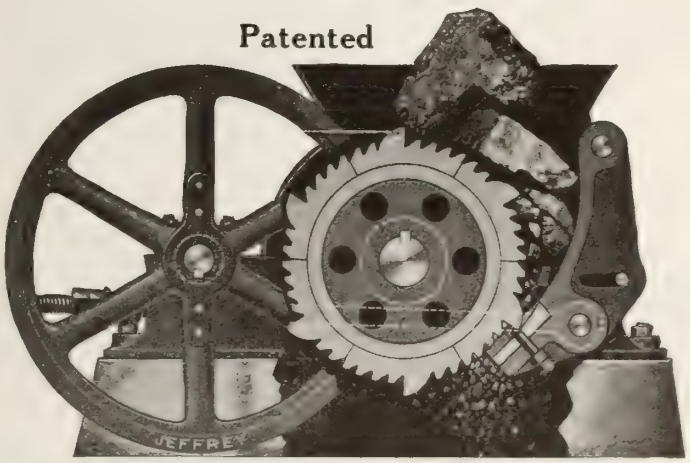
Arrangements were made with the railway officials by which the promised to place a car at the disposal of the Jeffrey company at Columbus at 4 p m., Friday, for the loading of the machine. It is expected that the crusher will arrive here some time Friday night. Steps have been taken to rush the installing of the crusher. Then the factories will be able to start up again.

Mr. Ashburner stated that the main trouble at the light plant was the inability of the company's employes to break up the coal fast enough to feed the boilers. Slack and nut can be used without crushing but such coal can not be obtained in sufficient quantities to keep the plant going at needed capacity.

EAST OHIO CITY
FEARS FUEL RIOT

Factories Were Closed Down Until a Jeffrey Single Roll Coal Crusher Was Installed

Patented



Power companies, traction companies and factories all over the country are having trouble, due to lack of **proper sizes** of coal for their stokers.

Meet This Situation as Many Companies are doing

Make Your Own Stoker Coal With Jeffrey Single Roll Crusher

Bulletin No. 141-A gives Complete Information.

OIL FILTRATION EFFICIENCY

The efficiency of any Oil Filtering and Circulating System is measured by the saving which it effects in oil and labor, in addition to reducing friction to an absolute minimum. This in turn depends on the capacity of the System to remove from the circulating oil, all foreign matter which causes friction, performing these operations with the least possible attention and little or no "upkeep." The ability of the System to do this depends on the efficiency of the clarifying and filtering devices.

In a

BOWSER
ESTABLISHED 1885

these features have been incorporated in the best possible relation to each other and in a manner which presents the best method for a commercially practical system.

Our engineers have an unequalled service to offer in Oil Filtering Problems, due to their thirty-three years' experience. This service is yours for the asking. Write to-day for complete information.

Don't buy that New Electrical Apparatus Just Yet

WE can supply you with high-grade apparatus that has been slightly used and discarded through no fault of its own, at an **immense saving in cost.** For instance, in many cases we take over entire plants simply because of changed conditions such as increased capacity, change of system, etc.

EVERYTHING IS OVERHAULED AND REFINISHED BY US AND **GUARANTEED** AS GOOD AS NEW, BOTH ELECTRICALLY AND MECHANICALLY.

Our catalogs of offerings should be in the hands of every power plant superintendent each time they are gotten out, and it will be worth while for anyone interested in this class of power plant equipment to be on our mailing list to receive **all** offerings.

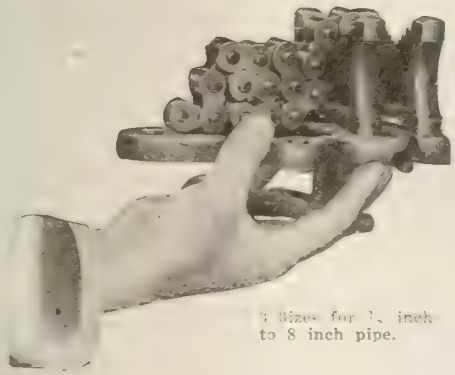
Nearly all of the principal power, lighting and street railway plants in the United States are our customers.

WRITE FOR OUR LATEST CAT ALOG of **Power House Equipment, Street Cars, Motors, Hoists, Compre ssors, etc.**

MACGOVERN & COMPANY, Inc.

114 Liberty St., New York City

Placed in the Hands of Power Engineers



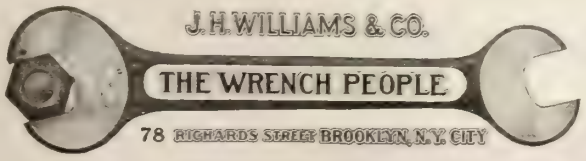
3 Sizes for ¾ inch to 8 inch pipe.

Williams "VULCAN" and "AGRIPPA"

CHAIN PIPE TOOLS

Readjust pipe disturbances in the beginning.

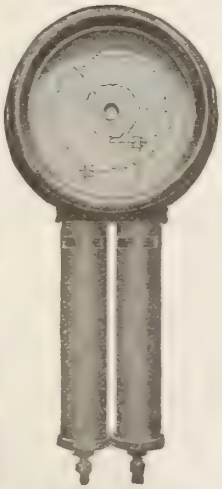
This inexpensive precaution that insures a minimum of interruptions and overtime repairs and frequently prevents heavy losses through leaks or explosions, is too vital a necessity to be ignored.



UEHLING WASTE METER

COMBINED

CO_2 AND TEMPERATURE RECORDER



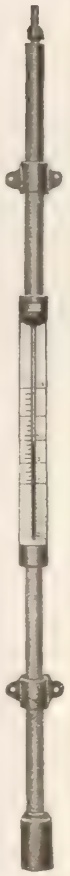
Record of CO_2 and stack temperature on one chart.

Does your fireman know how much fuel he is wasting? Do you know?

The **Uehling CO_2 Recorder** makes a complete 24 hr. record of your combustion efficiency and the **CO_2 indicator at the Boiler Front** holds the fireman responsible.

Get more **Steam** per pound of **Coal** and reduce your annual fuel consumption.

Let us know the number and size of your boilers and coal consumed per year, upon receipt of which information we will be glad to send you full particulars.



CO_2 Indicator for Boiler Front

Let us hear from you. We are pioneers in the manufacture of Indicators and Recorders for Power Plant purposes.

Send for our Bulletin No. 110.

Nationalizing the Distribution of Mechanical Rubber Goods

For the last thirty years users of Mechanical Rubber Goods have found their various needs most perfectly filled by such famous brands as:

Peerless Rainbow Belting, Rainbow Packing, Sawyer Canvas Belting, Eureka Fire Hose, Giant Steam Hose, Rinex Soles, Supremo Conveyor Belting, Holdtite Friction Tape, Peerless Honest John Packing, Relio Belting, Usco Radiator Hose, Rainbesto Packing, Buckeye Splicing Tape, Four Ace Seamless Belting, Paragon Fire Hose, Anaconda Tender Hose, Peerless Air Hose, Kold-Pak Jar Rubbers, Revero Garden Hose, Spring Step Heels, Giant Seamless Belting, Giant Suction Hose, Usudurian Packing, as well as hundreds of miscellaneous rubber items, such as rubber soles and heels, rubber tiling, matting, mats, plumbers' supplies, rubber thread, rubber toys and golf balls.

Now, to effect that close co-operation between manufacturing and distributing required by the great growth of this nation's industries and its demands for mechanical rubber goods of recognized quality and workmanship, we have established branches in all principal cities.

These, plus the quick facilities of our factories advantageously located in the big centers East and West, constitute a nationalized service that our friends and users will find adequate to meet every occasion.

To make identification of these goods doubly easy and absolutely certain, all of these well known brands still carry their old and familiar trade-marks, and in addition the great United States seal, the hall mark of quality of the largest rubber manufacturer in the world.

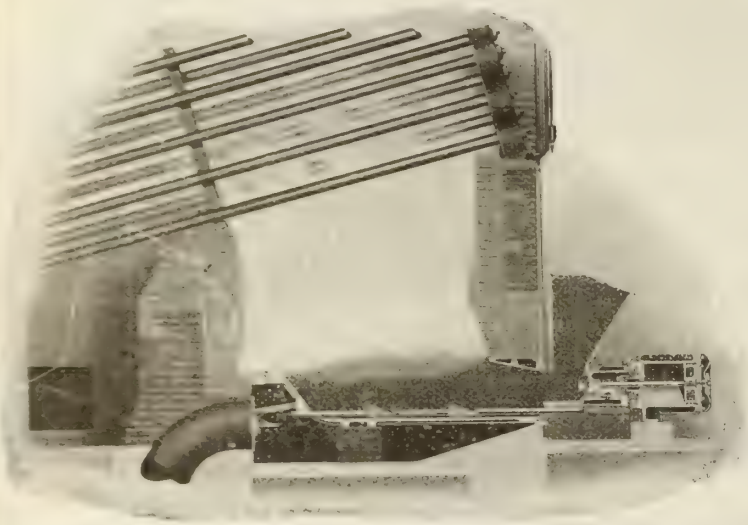
JONES UNDERFEED STOKER



keeps down the fuel bills

Burns less coal and cheaper coal.

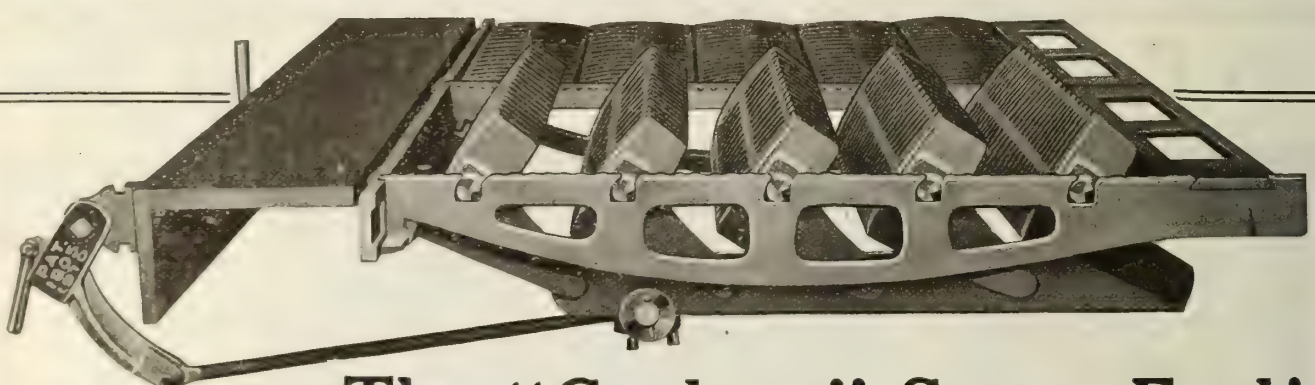
Gives you complete combustion and a smokeless stack —you can get a steady steam pressure regardless of your loads. Hundreds of Jones Stokers are making **fuel savings from 15% to 25%** in plants like your own.

They are the simplest stokers built. No grates to lose fuel through and few working parts, none of which move in contact with fire.

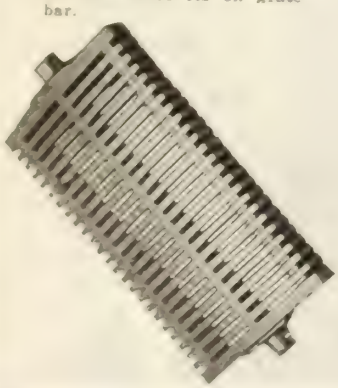
It will pay you to get in touch with us.

Saving money is making money.

Jones Underfeed Stoker Co. Ltd.
37-41 Britain Street, TORONTO



1—Note new jarring, shaking movement whereby ashes are shaken off centre of bar without letting good fuel into ash pit.
2—Note new lock frame.
3—Also new coupling device.
4—And centre rib on grate bar.



The "Cyclone" Saves Fuel!

About the most patriotic move you can make just now is help conserve Canada's coal supply. There may be a crisis next winter! CYCLONE SHAKING AND DUMPING GRATES SAVE FUEL—tons of it in a few weeks. Burns low grade fuel—every bit of it—with maximum results. This is accomplished by 60% air space and 90% underdraught, a feature of CYCLONE construction. No waste.

THIRTY DAYS TRIAL—This is the confidence we have in the Cyclone Grate. Easy to put in, no shut-down necessary. Let us hear from you.

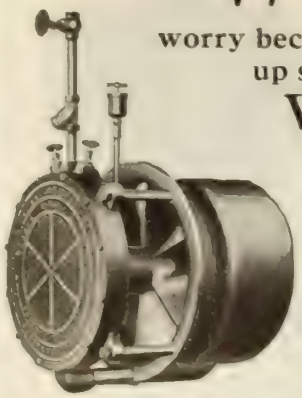
WHY

worry because you cannot keep up steam pressure

WHEN

it is so easy and cheap to overcome your difficulties by installing a



COPPUS TURBO BLOWER

It means constant steam pressure, regardless of uneven loads, poor draft and poor coal, and it will pay for itself in a short time on account of better combustion. It also will increase your boiler capacity to 200, and even 300%, of its normal rating without injury to the boiler. Cut out this Ad., put your name and address on the margin and mail to us. Without further trouble you will get all the particulars.

500,000 H.P.

In boilers equipped with Coppus Turbo Blowers in four years. The Coppus has replaced a great many other blowers, but no other blower has ever replaced a Coppus.

When Buying Thermometers

There's Just Three Things to Remember—

First, you must have accuracy and sensitiveness—

Second, durability is absolutely essential—

Third, the thermometer must be suitably constructed for the intended application.

Accuracy, sensitiveness and durability are absolutely guaranteed in

"Crescent" Thermometers

And with nearly seventy years of experience to our credit, we are qualified to properly interpret your needs.

Our Catalog P.H. 200 illustrates and describes "Crescent" Thermometers for every application. Also test thermometers, glass thermometers, etc.

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compressors

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction.* Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under any unforeseen strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satisfactory operation, but practically *eliminates expensive shut-downs.* Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring oiled bearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

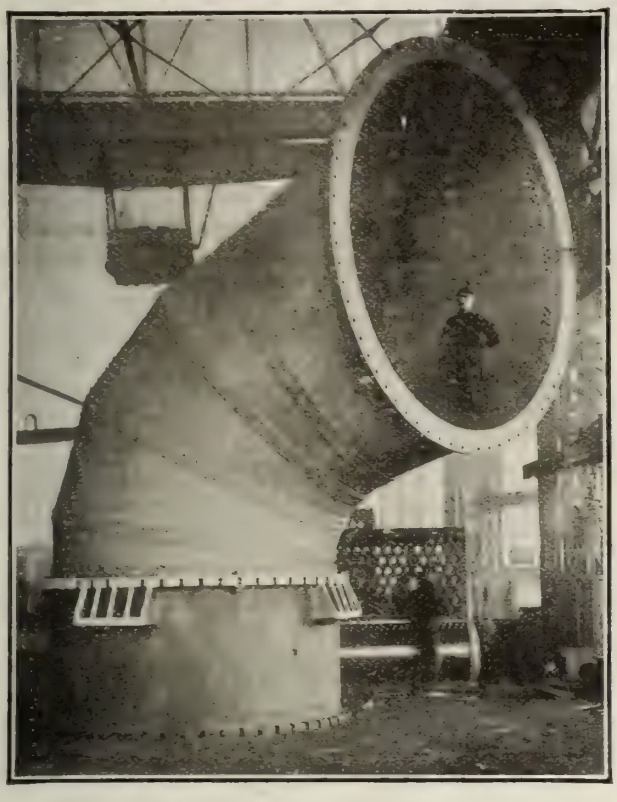
Plate and Boiler Work



Steel Plate Penstock Elbow

WE have the largest and best equipped plate shop in Canada, and make a specialty of heavy and difficult plate work. A good example of this is shown in accompanying illustration of a large penstock for one of the Niagara Falls power plants, 10 ft. 6 in. in diameter at the bottom and turning to an elipse at the top 12 ft. 10⅝ in. high and 11 ft. 8⅛ in. wide.

The Canada Water Tube Boiler is adapted for power plant service of all descriptions for steam pressures up to 150 lbs. The addition of the superheating drum insures absolutely dry steam under worst conditions, and normally delivers steam superheated from 10 to 30 degrees without external superheater. The circulation is theoretically correct. It is built in sizes from 100 to 500 h.p. per unit.

Return Tubular Boilers are built in all sizes allowed by the different Provincial Inspection laws and are built under Ontario Government Inspection. Either horizontal, vertical or locomotive portable types are furnished.

WE have the exclusive right to manufacture and sell in Canada the Steam Specialties of the Harrison Safety Boiler Works, including their complete lines of Cochrane Open Feed Water Heaters, Independent Meters, Steam and Oil Separators, Multiport Safety Exhaust Outlet Valves and Sorge-Cochrane Hot Process Water Softener.

We have also similar rights for Squires' Steam Traps, Pump Governors and Reducing Valves.

Hooverizing Refrigeration

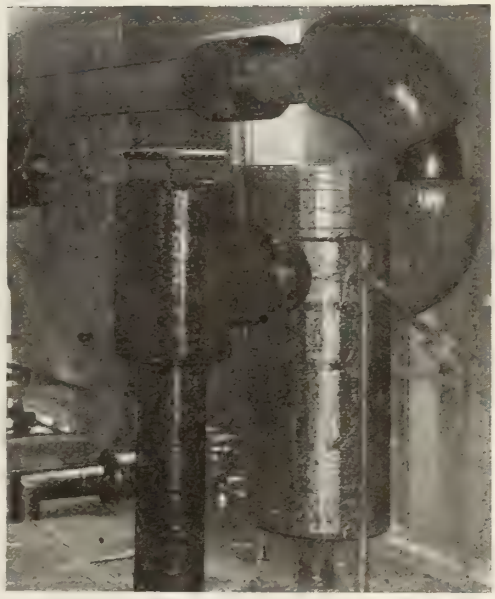
In these days of high operating costs you need no administrator to impress upon you the necessity for stopping all preventable loss in your plant. Your own sound business judgment tells you that that is the logical course. But how can it be accomplished?

One of the leaks which should receive your earliest attention is the loss of refrigeration from bare or improperly covered brine and ammonia lines, coolers, etc. This waste is hard to measure because it cannot be seen or felt; but it exists nevertheless. For instance, do you realize that only 176 feet of 2-inch bare pipe carrying brine at 15° F., with the surrounding air at 75° F., will lose one ton of refrigeration per day? At the low cost of 75 cents per ton, this loss would total $270.00 per year.

By applying Nonpareil Cork Covering of the proper thickness, about 80% of this waste would be eliminated, and approximately $216.00 would be saved the first year —more than enough to pay the cost of the covering. After that, this saving of $216.00 per year would be practically clear profit.

Nonpareil Cork Covering

For All Cold Pipes



Brine line and tank insulated with Nonpareil Cork Covering. The Artificial Ice & Storage Co., Canton, O.

All the assistance that many years of experience can give is at your disposal, just for the asking. Our 64-page, illustrated book, regarding Nonpareil Cork Covering, would be of especial interest to you, we believe.

The Publisher's Page

TORONTO MAY, 1918

THERE is a special treat in store for our readers next month. Our June issue this year will be our Annual C.A.S.E. Pre-Convention and Annual Equipment and Supply Directory Number. It will be doubly interesting and doubly valuable since the editorial pages and the advertising sections will vie with each other in quantity and quality of instructive information.

Our editors have arranged a special programme, including several articles on leading power plants in the city of London (Ont.), where the 1918 Convention is to be held. There will, of course, be C.A.S.E. features and the regular departments will be even brighter and more instructive than usual.

Manufacturers of power equipment and supplies recognize the importance of our annual number and many arranged for extra space in which to present for the consideration of the engineers a description of their lines which will not only do them justice but which will enable engineers to become thoroughly familiar with them and their respective merits.

Engineers are more and more learning to appreciate the advantages of intelligent instructive advertising—this is as it should be. An engineer's work deals very largely with engineering equipment and the necessary supplies to keep it running.

Advertising deals with the same thing exactly. Moreover, the advertising appearing in POWER HOUSE is placed there by firms manufacturing good products and marketing them through a good medium by appealing to good engineers. These firms recognize the buying influence of even obscure engineers, and the compliment will not be lost upon the thoughtful observing members of the profession.

Last month we published a letter by John Hale, ex-secretary of the C.A.S.E., two paragraphs of which we would like to reproduce herewith:—

> Speaking for other engineers with whom I have talked, as well as for myself, I can say that POWER HOUSE Buyers' Directory is invariably consulted when supplies are needed. If the average engineer does not mention POWER HOUSE when writing to advertisers it is probably because they do not think it necessary or they may forget to do so. Of one thing I can assure you and that is our members certainly prefer goods advertised in POWER HOUSE to any others.
>
> I would like to mention the exchange of views among the engineers through the medium of POWER HOUSE. If Canadian engineers would use the pages of POWER HOUSE to exchange their ideas more one among the other, they would be not only benefiting themselves but would be helping those less fortunate. We have in Canada engineers who will compare with any engineers in the world and I feel that there should be a greater exchange of ideas and I am taking this up with our members at once.

We urge you to study the advertising pages, not merely to read them. Use them as you would a text-book because that's what they are—a text-book of modern power plant equipment. Not complete, perhaps, but extremely valuable and becoming increasingly so. If manufacturers do not give you the kind of information you would like and need tell us. Or better still, tell the advertisers. They'll appreciate it, and thank you for your suggestions.

And finally, help other engineers, help us and help yourself by contributing your ideas to POWER HOUSE. Every engineer has a pet scheme or idea which should be passed on. Pass it on, friend, and multiply its usefulness, yours and ours.

POWER EQUIPMENT

Built to Meet Your Own Requirements

PART I.

The many uses for power in the various metallurgical operations connected with the refining of metals necessitate more than usual provision for adequate and unfailing supply. The following article deals with the steam plant auxiliary of one of the largest smelters in British Columbia.

THE power plant of the Granby Consolidated Mining, Smelting & Power Company, Ltd., at Anyox, B.C., where their copper mines and smelter are located, consists of a hydro-electric power plant, known as No. 1 power house, which furnishes power for the various operations of the company. During a period of about five months in the winter, however, the water supply is not sufficient, and a 6,000 horse-power auxiliary steam plant has been installed. It is this auxiliary steam plant which is dealt with in this article.

The distributing switchboards are in No. 1 power house, the power generated being used for general lighting, several large electric cranes at smelter, electric locomotives taking ore to the furnaces and waste from the mine, for supplying compressed air for converters, furnaces for drilling operations at the mine, motors running machinery at the machine shop, crushers at the mine, and coke hoists at the wharf. As there is also between 6 and 7 miles of track, with several 42-ton locomotives, this will give a general idea of how the power is expended.

Anyox, which is at seaboard situated on Granby Bay, is in Northern British Columbia, being approximately 1,000 miles north of Vancouver, and 100 miles from Prince Rupert, the latter town being the largest of any importance in northern British Columbia.

The auxiliary steam power plant is rated at 6,000 h.p., and while the No. 1 power house or hydro-electric plant is the larger, the writer believes that a description of this auxiliary plant may be of greater interest to the steam engineer. The way in which the plant is arranged, and instruments installed, along with numerous observations made by the writer on the performance of the plant may be of value for comparison with other plants somewhat similar.

Building

The main building is constructed of reinforced concrete with a dividing wall between boiler and engine rooms. The approximate size is 84 ft. 7½ ins. wide, by 175 ft. in length and about 50 ft. high, the dividing wall running through the centre of the building lengthwise. The floor is finished in slabs of concrete 2 ft. square, finished with iron cement surface, which is essential where heavy machinery is being installed.

The main floor of engine room is raised about 15 ft. above the level of boiler room, the engine room basement being on a level with the boiler room floor.

Addition to No. 2 Power House

The machinery in the addition was formerly in No. 3 power house, was housed in a frame building adjoining No. 2 power house, but this building was pulled down and an extension added to No. 2 power house, this extension being the same height and witdth as No. 2 power house, and about 78 ft. long, with ing into boiler and engine rooms—boiler room being 26 ft. 7 in., and engine room 40 ft. 6 in., the length of these being the same as No. 2 power house, 84 ft. 7½ ins. Along the sides of the main building of the annex are concrete piers running from floor to roof at 14 ft. 1¼ in. centres, these piers being 12 ins. broad and projecting from the wall about 14 ins. The lighting throughout is so arranged that splendid results are obtained by means of powerful nitrogen lamps with inverted shades and reflectors.

Boiler Room

There are five Babcock & Wilcox water-tube boilers, rated by the makers at 550 boiler horse power, or a total of 2,750, and having an approximate heating surface of 5,550 square feet each.

These boilers have double drums, 48 in. dia. by 23 ft. 6 in. long, and are fitted with superheaters, each boiler having 252 4 in. tubes 18 ft. long. The boilers are fitted with Crane 7 in, non-return balanced stop valves, which will not open until the pressure on the outlet side and in the boiler are balanced.

In a battery of boilers, if the attendant stops firing on one boiler that boiler will cut itself off the line as soon as the pressure drops on account of the pressume on top of valve from other boilers being greater than the pressure in the boiler with the fires off, and

STAFF AND EMPLOYEES OF MECHANICAL DEPARTMENT, GRANBY CONSOLIDATED MINING, SMEITING AND POWER CO., ANYOX, B.C.

while this lessens the danger when opening large stop valves under high pressure, the makers furnish a caution plate which should be fitted on every main stop valve. This plate reads, "Drain superheater before opening this valve."

The superheater pipes are flooded from a pipe connection to the water space on the side of the drum and before starting to fire a boiler the superheater should be flooded by opening flooding cock on this pipe. When steam is up another cock coming from superheater drain should be opened to drain superheater, first closing the flooding cock. It takes at least 20 minutes to drain the superheater which is shown by small square glass fitted on superheater drain, so that one can see whether steam or water is passing. The drain cock should now be closed, and when the pressure on the boiler which is being cut in is nearly the same as the others already on the header, the main stop valve can be opened slowly.

The B. and W. boilers are well known, but for those who have not had experience with this type of boiler with superheater, a description of the method of draining superheater is well in order, as those who have had this experience will know.

Safety Valves

Each drum is fitted with two 3 in. McAvity safety valves, and as there are two drums to each boiler this makes four 3 in. safety valves for each. In order to comply with the Boiler Inspection Act of this province the boilers carry 175 lbs., but are allowed 217 lbs. per square inch. Safety valves in this province are not locked with key and padlock by the inspector. The control of safety valves is left to the engineer, but if he carries more pressure than allowed by the boiler inspector's certificate for boiler he is quite liable to have his engineer's certificate cancelled.

There are several features necessary for safety valves to comply with boiler rules here. The seat must be locked in some way, usually a ¼ in. or ⅜ in. set-screw, screwed from outside casing into thread of seat which keeps lower portion of seat from getting out of place. The valve lift is ⅛ in. to each inch of valve diameter, so that for a 3 in. safety valve the lift would be ⅜ in.

GENERAL VIEW OF BOILER ROOM—5 B. AND W. BOILERS OF 500 H.P. EACH.

Steam Header

The steam header is 12 in. diameter and 55 ft. long. Boilers are connected to header by 7 in. pipes forming S bends. Directly behind No. 1 boiler, near the end of header, is a 6 in. valve for pipe running to feed pumps, oil pumps, etc. Next in order are an 8 in. stop valve for No. 1 turbine main unit; 7 in. stop valve for No. 1 boiler; 7 in. stop valve for No. 2 boiler; 4 in. stop valve for exciter unit; 4 in. valve for No. 1 unit auxiliaries; 7 in. stop valve for No. 3 boiler; 6 in. valve for No. 2 turbine main unit; 7 in. valve for No. 4 boiler; 7 in. valve for future unit; 3 in. valve for No. 2 turbine auxiliaries; 7 in. valve for No. 5 boiler; 4 in. valve for No. 3 compressor unit. As before mentioned each boiler has a 7 in. balanced stop valve directly on top of boilers, which makes one valve on boiler and a stop valve on header for each boiler. There are two 2 in. blow-off pipes from mud drums of boiler, with a 2 in. asbestos packed cock on each pipe and a quick-opening 2½ in. valve or disc valve on each boiler. The superheater 1¼ in. drain pipe on each boiler is also connected into blow down pipe.

Boiler Feed Pump

There are two boiler feed pumps which consist of DeLaval steam turbines direct connected to DeLaval 3-stage centrifugal pumps running 3,300 revs. per min.

BLAKE AND KNOWLES OPEN FEED WATER HEATER OF 3,000 H.P. RATING.

Steam pressure into turbine is 175 lbs. per sq. in. and exhaust is at atmospheric pressure. Capacity of each pump is 180 gallons per minute ,and water pressure carried is about 250 lbs. per sq. in.

One very noticeable feature of this installation is the small amount of space occupied. The base of each pump is only 42 in. long by 24 in. wide, sitting on a concrete foundation 12 in. high. The total height of installation from floor, including base, is about 36 in. There is a 3 in. steam pipe to each pump and a 6 in. exhaust, which exhausts into the feed water heaters.

The suction to pumps from heater is a 6 in. header branching into a 3 in. pipe to each pump. Discharge is 2½ in. from each pump branching into a 4 in. pipe, this 4 in. pipe running to and along the top of boilers with a 2 in. pipe branching off to each boiler. Each branch has a 2 in. gate valve near water header, then there is the regulating valve with a long rod attached to valve spindle which the fireman can reach from the boiler-room floor below for regulating the feed water into the boiler.

Near the steam drum on the feed line there is a 2 in. combination stop and check valve, stop being next to boiler. There is a water gauge glass on each drum and chains reaching the floor which are attached to extension rods and levers so that in the event of a glass breaking the water and steam can be shut off from the floor. A fusible safety plug is on the side of the drum about one-third the distance from the bottom of drum.

Pump Governors

The feed pumps are fitted with two governors—the running governor, in which the steam pressure is on one side of a piston and the water pressure from discharge of pump on the other side, and by means of a spring and regulating nut the pump can be set to keep any desired water pressure within the limit of the pump. The other or emergency governor consists of a spring and small weight fitted into the shaft of the turbine, and if pump exceeds its speed the weight flies out and trips a lever which in turn allows a steam valve held by a small spring to drop down and close off the steam to the pump. To start the pump again the throttle valve must be first closed, then drain the steam out of line by means of ¼ in. valve near pump, then push up the valve which has the small spring under it and set lever up to keep valve from falling down, then start pump slowly by opening main throttle valve.

One of these pumps supplies water for the entire battery of boilers and is kept running continuously when plant is operating, the fireman opening and closing regulating valves on boilers according to demands for water, but never having any occasion to touch feed pump except to see that bearings have oil, as the pump will maintain whatever water pressure the governor is set for.

Fuel Oil Pumps

There are two Worthington duplex pumps, 6 in. x 4 in. x 6 in., used for supplying fuel oil to the oil burners. The pumps are fitted with Aston governors consisting of species of T-pieces in the steam pipe. The steam pressure comes on the side of a valve in the pipe, which has a spindle projecting through one opening of the T through a packing gland and nut. This spindle extends right to a diaphragm which receives the pressure of oil from discharge side of pump. On the spindle near diaphragm there is a spring and compression nut, so that by increasing or decreasing the compression on the spring by screwing the compression nut in or out, the pressure of the fuel oil is kept constant, and when the governor is working properly the variation of pressure does not exceed two pounds.

Another point which may be worth mentioning about the oil pumps is that most of them have some form of metal packing for the plungers on the oil end. In this case there are white metal rings about ½ in. thick. The writer once had a boiler feed pump handling the returns from a paper machine, and tried several kinds of packing, all of which lasted hardly twenty-four hours. Finally the plungers were taken out and the space for packing was filled with babbit. The plungers were then turned up in the lathe to fit the barrel and this pump was still working well a year afterward at least, to the knowledge of the writer.

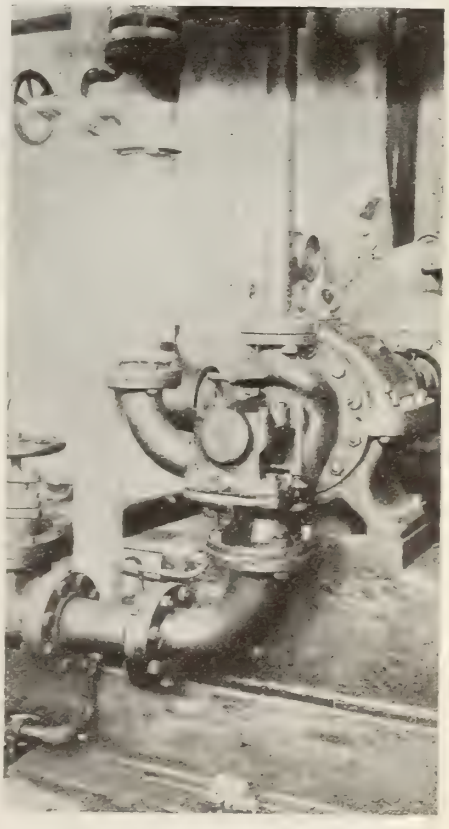
The steam pipe to each pump is 1 in. diameter, the pressure being lowered by a Crane reducing valve from 175 lbs. to 125 lbs. The exhaust pipe is 1¼ in. and exhausts through an oil heater under pumps and out to atmosphere. The suction pipe to pumps is 3 ins. and discharge 2½ ins. The oil tank directly outside power house has a capacity of about 200 barrels, while the main fuel oil tank has a capacity of 34,375 barrels. Diameter of tank is 19 ft. 3 in. by 29 ft. 8½ ins. high.

Fuel Oil Burners

The oil burners used in the furnaces are the Peabody back shot type, that is, the tip of burner is led to back of furnace and flame shoots forward to front of boilers. The furnace is a Peabody furnace, this arrangement of furnaces and burners being furnished by Babcock and Wilcox Company. There are three burners to each furnace; fifteen in the entire battery. Oil pressure to burners averages about 80 lbs. per sq. in., and oil temperature runs about 190 degs. Fahr. to 200 degrees Fahr.

The type of burner is known as the external mixing type. A ¼ in. pipe carries the oil to the tip of the burner and is inside another pipe which is 1 in. dia., this larger pipe carrying steam to the burner tip and at the same time heating the oil. There are two slots in the burner tip, the oil coming out of the top one and the steam coming out of the lower slot. The steam comes out and spreads in the form of a spray and the oil coming out of slot drops on to the steam spray and in this way the oil is broken up or atomized. Fire can be started easily by a piece of lighted waste.

It takes considerable study to burn fuel oil properly so as to get good re-



HOTWELL AND AIR PUMPS OF NO. 1 UNIT; NOTE 2-INCH EQUALIZING PIPE ENTERING TOP OF PUMP.

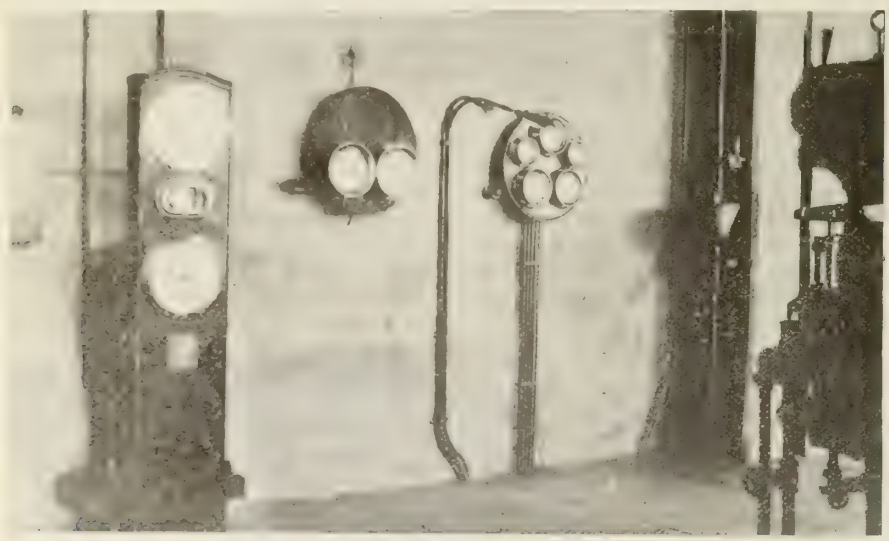
sults, but there are several simple precautions that everyone who attempts to burn oil in a furnace should know or they are likely to do damage or get badly burned. First thing, be sure and open your dampers before starting fire, then turn on steam or air or whatever the atomizing agent may be, blowing through the burner in order to get clear of the water of condensation either in the compressed air or the steam.

Automatic Fuel Oil Control and Damper Regulator

This system of fuel oil and damper regulation is known as the Merit system and was supplied to the plant by the Associated Engineering and Supply Co., San Francisco. It consists of two controllers known as master controllers, with a regulator on each fire and damper, and is much the same in principle as the governor just described on the fuel oil pumps. The fire is operated in three stages: the pilot, or very small fire which is regulated by hand and takes care of the minimum load; then a medium fire, which takes care of the average load of the plant; and the maximum fire which takes care of the largest load the plant will carry. The fires are set by raising steam to highest point. In the plant in question carrying 175 lbs., first raise steam above 175 lbs., then set small fires by hand. When steam drops to 174 lbs. set medium fire, and when steam drops to 173 lbs. set large fire.

The master controllers have the steam pressure acting on top of a diaphragm and oil acting on oil valve at bottom of controller. There is a spring and a compression nut so that the controllers can be set to cut in at whatever pressure is desired, and when steam gets too high controller is put out of action and shuts off control oil to regulators. As soon as steam pressure drops about one pound medium fire will cut in, also medium position of dampers, both front and back dampers, which are operated by regulator and big rods and a weight on a stack damper; then if steam drops about another pound or to 173 lbs. large fire will cut in and dampers will open to suit maximum fire, and when steam rises large fire will cut out, and if it rises further medium fire will cut out, and as the pilot fire is just large enough to keep fires alight the steam will begin to drop; then the medium and later high fires will cut in, and in this way a steady steam pressure is maintained, and even though in this plant the load varies from 200 to 1,600 horse power every few minutes, the regulators maintain a steady steam pressure, with less than five pounds of a variation for the entire day of twenty-four hours.

Before leaving the subject of oil burning, I quote a writer on oil burning named Booth, who says "where you have a properly constructed furnace better results can be obtained firing the oil into furnace with a shovel than can be had with a poorly constructed furnace and the highest type of oil-burning apparatus." The foregoing is a strong statement, but I have found this correct, for where your furnace is poorly laid out good results can not be obtained. The air spacing is most important, that is, allowing air to come up through the space left between the brick on top of grates at the proper place with regard to the flame. Very often an oil-burning fire can be set to burn, but if that boiler had to be set to give proper results, checking same up with a CO_2 recorder, you might find that you were burning double the amount of fuel you ought to burn to give the results you were producing. However, the writer will touch on C. O. recorders in a later portion of the article. The temperature and pressure of the fuel oil are also important, and in numerous tests made by the writer from 190 degs. Fahr. to 200 degs. Fahr. gave the best results.



SHOWING VENTURI WATER METER, STEAM AND PYROMETER GAUGES AND GAUGE BOARD FOR NO. 1 TURBO-GENERATOR UNIT.

Burning Fuel Oil

The following poem relating to oil fuel regulation has reference to British destroyer service, and the writer observed it in the "Victoria Daily Times," October, 1916. It is reprinted here because of its aptness, the rhyme and rhythm making it easy to remember:

"Set the burners open wide,
Do not touch the valves at side.
Keep the pressure on the pump
And up the bally steam will jump.

"If the smoke is black and thick,
Open up the fires a bit.
If the smoke is thick and white,
To slow the fans will be quite right,
For when sufficient air is given
No smoke ascendeth up to Heaven.

"If the jets refuse to squirt,
Assume the cause is due to dirt.
If the flame be short and white,
You have combustion clear and bright,
But should the flame be yellow and long,
Combustion is entirely wrong.

"A wise man to his heater sees
And keeps it at 200 degrees;
To have it more is not quite wise
Because the oil may carbonize.
A little lower has been found
To give as good results all round.

"If the filters are kept clean
No rise of pressure will be seen,
But, should the pump kick up a ruction,
There's likely air within the suction.
The pressure governs the supply
So do not keep it very high.

"If these instructions you will follow
You'll beat the other fellow hollow."

(To be continued.)

GAS FROM STRAW

THREE Prairie Provinces in Canada produce every year 20,000,000 tons of straw. This straw is at present regarded as having no commercial value and is burned. A retort has recently been invented in which the straw is carbonized and thus decomposed into combustible gases, tar, and ammonia. A number of experimental plants have been made, and it is hoped to get them installed on a certain number of farms during the present winter. The gas thus obtained will be utilized by the farmer for purposes of lighting, heating and power, thus producing useful fuels from hitherto waste material.

The retort is made out of highly refined steel and is designed in such a shape that the gases are removable in a very short time; it is also designed for individual use on the farm and is of small dimensions. It consists of three oval cylinders 7½ feet long, with a major axis of 24 inches and a minor axis of 6½ inches, the retort being enclosed in a metal or fire-brick casing with a fire box below. With a scrubber and a gasometer the total cost including installation is expected to be $500.

The straw, compressed into bales the size and shape of the retort, is placed

in it, the doors are shut by a clasp, and straw burnt in the fireplace below. After the operation when straw is used as a fuel, a certain proportion of the gas given off is used for the purpose of the carbonizing process, about 30 per cent. of the total volume of the gas being utilized in this way. The gas begins to come off at a temperature of 200 deg. C. and reaches its maximum between 500 and 600 deg. C. All the gas may be removed from the straw in about 30-45 minutes, rapidity of operation being an important factor from a commercial standpoint.

Each ton of straw produced between 11,000 and 12,000 cubic feet of gas, the quantity and the quality of gas varying slightly from different kinds of straw. The gas after generation in a retort passes into a scrubber (this being a metal cylinder 4 ft. long. by 18 or 20 ins. diameter), and thence into the gas container or flexible bag. If the gas is washed and purified so that the volume is reduced to 10,000 cubic feet, and, as stated above, 30 per cent. be utilized in carbonizing a ton of straw, there would be a surplus of 7,000 cubic feet for every ton of straw carbonized. The calorific value of straw gas is approximately 400 B. T. U.'s per cubic foot, so that one ton of straw would contain 4.000.000 B. T. U's. In this country we reckon that about 250 feet of coal gas is equal to one gallon of petrol, and the thermal value in B. T. U's of a gallon of petrol is calculated in the States at approximately 114,000. In this country we give it a higher value. Taking 7,000 cubic feet as the net output from a ton of straw, the heating value of the gas from that quantity of straw would be 2,800,000 B. T. U's, which can be taken as equivalent to 25 gallons of petrol.

From every ton of straw there is obtained between six to eight gallons of tar and ammoniacal liquors. This tar in its crude state would pay for the cost of baling the straw, which may be approximately put down as 4s. 6d. a ton, so that the farmer would have his fuel prepared ready for use at the cost of hauling it from the field to his retort. The carbon residue, of which there is about 600 pounds to a ton of straw, would find a ready sale as lamp-black.

As indicative of the importance of the scheme in the U. S. A. or Canada it may be mentioned that on the 20,000,000 acres which are cropped annually in the three Prairie Provinces of Western Canada only, and giving a yield of one ton of straw per acre, there is a total yield of straw of 20,000,000 tons. Allowing for washing and purifying and for the use of about 30 per cent. of the gas for the purpose of carbonizing the straw, there would be procurable 140,000,000,000 (one hundred and forty thousand million) cubic feet of gas, which may be taken to be equal to 22,000,000,000,000 (twenty-two million million) h.p. hours.

NAPHTHALENE AS MOTOR FUEL

By L. E.

THE effect of the compulsory search for a substitute for petrol has been highly beneficial, as it has stimulated experiment and test in directions which would otherwise have been neglected under normal conditions, and research has revealed that coal provides an excellent hydrocarbon which can be utilized as fuel for the internal combustion engine: benzol. But this product is indispensable for war purposes, so it was promptly ruled out of court. Yet benzol is but one of the many hydro-carbons derived from coal, although it is admittedly the most acceptable substitute for petrol, as a fuel for the explosion motor. But coal possesses other constituents of a similar character, although somewhat heavier, and amongst these must be mentioned naphthalene, a substance which, while not popularly known under its technical name, is familiar enough.

Naphthalene is a crystal. In its crude condition it might also be compared to dirty, finely-powdered snow, being relatively light and fine in its consistency. In this condition it contains a certain proportion of creosote oil, which imparts an oleaginous character to the substance, but which can be driven out by subjecting the powder to a violent centrifugal or whizzing action, and can be further cleaned or rectified by washing with an acid. But naphthalene is the bugbear of the gas engineer, and of the householder, who depends upon coal gas for illumination. With a slight drop in temperature it condenses in the form of snow and becomes an obstruction in the pipe. A very small quantity suffices to impede the natural passage of the gas, and recourse to the force pump or a liquid solvent are the sole effective palliatives. Apart from its conversion into dyes and carbon blocks and moth balls, naphthalene is of little use except possibly for the preparation of firelighters, to which latter purpose about 50% of the total yield is devoted.

In pre-war days crude naphthalene commanded about $20 per ton, and although the current price is from $25 to $35, its reclamation cannot be described as profitable. The annual yield in the aggregate from the gas and tar works of the British Isles is equivalent to about 10,000,000 gallons. Yet naphthalene is closely allied to the more appreciated hydro-carbon, benzol, and it belongs to the same series. The chemical symbol for benzol is $C_6 H_6$, that for napthalene is $C_{10} H_8$, and this close relationship was responsible for the doping practice which had a certain vogue during the early days of benzol as a motor spirit. This fact was also responsible for another line of action amongst certain French and German investigators. They advocated the possibilities of the compound as a fuel for internal-combustion engines, and carried out experiments to support their assertions, but they never achieved distinct success. The general practice was the dissolving of the naphthalene in a lighter hydrocarbon such as petrol or benzol. These two liquid fuels will readily absorb a certain portion of napthalene, the quantity varying from 20 to 40 per cent. But the experiment did not prove successful in practice.

Success in Sight

Other inventors, confident of their ability to use napthalene as a straight fuel, confined their efforts to achieving success in this direction, but other difficulties arose, and success was not forthcoming. But to-day it seems as though success is within a measurable distance of turning this elusive by-product of coal into a commercial motor fuel, and that without recourse to doping or other expedients.

Some five years ago two English experimenters, Mr. J. H. Willis, and Lieut. G. G. Wilson, attacked the problem. Their investigations elicited one important fact and they resolved to continue their researches from point where text books left off. These had settled that the melting point of the hydro-carbon was 79.8 degrees C., and the laboratory experiments were conducted on methodical lines from this point, and these proved conclusively that it was necessary to raise the temperature to about 133 deg. C., in order so highly to change a small volume of air into naphthalene vapour that sufficient would be present in a form suitable for an explosive mixture with a large proportion of air subsequently introduced. It was also found that the explosive mixture was formed when composed of 12 parts of air to 1 of naphthalene vapour.

A special form of vaporizer had to be devised and subsequently the vaporizer, carburetter and fuel tank were combined. With the experimental installation, starting up is conducted on petrol. After running for about ten minutes by which time the naphthalene has been melted and raised to 275 deg. F., the petrol is shut off and the napthalene vapour switched on.

LUBRICATION OF SHAFTING

TO obtain efficient lubrication a film of oil only is necessary, and to get this without waste the old dodge of using twisted worsted or cotton yarn is hard to beat when properly used. The methods of application differ, although the principle is the same in all cases. A receptacle partly filled with oil forms the reserve supply, and in this there is one end of a loosely spun thread of cotton or woollen yarn, the other end being in contact with the shafting or other part to be lubricated, the oil being drawn over by capillary attraction.

The rate at which the oil passes depends partly on its viscosity and partly on the tightness with which the yarn is spun, while for some purposes a flat woven lamp wick very well supplies what is needed. No large amount of oil is needed for well-balanced machinery which is not overloaded, provided the right quality of oil is used, but it is necessary that the supply be continuous or lubrication will be inefficient. A flood of oil for half the day and dry bearings for the other half is almost as bad as no oil at all, and is avoided in good practice. It is wasteful of lubricant and harmful to the plant.

Electricity and Hydraulics

PRINCIPLES AND OPERATION OF MODERN ELECTRICAL EQUIPMENT—III

By A. M. Pere

THE electrical units dealt with in the previous section, namely, the volt, measuring the potential difference; the ampere, measuring the rate of flow of the current and the ohm, measuring the resistance with which a circuit opposes the flow of electricity, are connected by a simple relation which is easily understood when the definitions of these units are considered.

The volt is the unit of electrical pressure or potential difference which causes a current of one ampere to flow through a circuit having a resistance of one ohm.

When a current flows through a circuit having a resistance of one ohm and under a force or voltage of one volt, the value of the current is said to be one ampere.

When an e.m.f. or voltage of one volt causes a current of one ampere to flow through a resistance, the resistance is said to have a value of one ohm.

Ohm's Law

It is seen that all three of the above definitions are mutually dependent and all three are only different ways of expressing a simple relation known as Ohm's law, which may be stated thus:

The amount of current, in amperes, flowing in an electric circuit can be determined by dividing the e.m.f. in volts by the resistance in ohms of the circuit.

This relation may also be expressed in the form of an equation:

$$\text{Current} = \frac{\text{e.m.f.}}{\text{resistance}}; \quad \text{amperes} = \frac{\text{volts}}{\text{ohms}};$$

$$\text{or } I = \frac{E}{R}$$

In the last of these three forms the letters commonly used as abbreviations are put down. E stands for e.m.f. or voltage; R for resistance in oms and I is used for current, since C has been reserved for another unit little known in commercial usage.

Ohm's law is a most important one and is useful in almost any electrical problem. It is used for direct current and applies when a steady flow of current has been established. In alternating current work other factors enter into consideration which modify the above law under certain conditions. Ohm's law may be used, however, and is correct in the above form when working with single phase alternating current circuits at unity power factor.

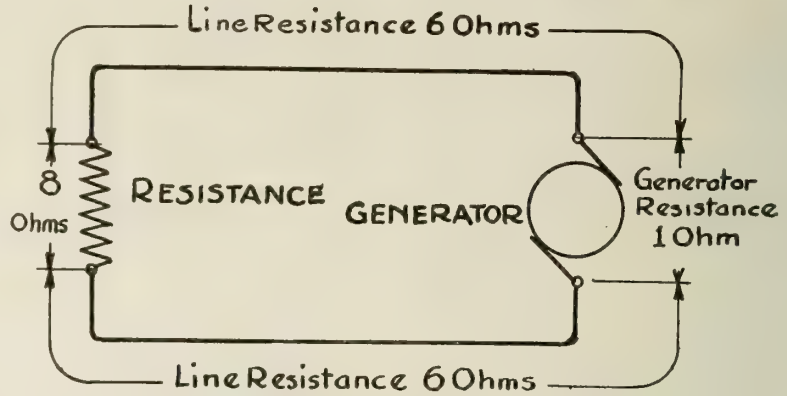


FIGURE 1.

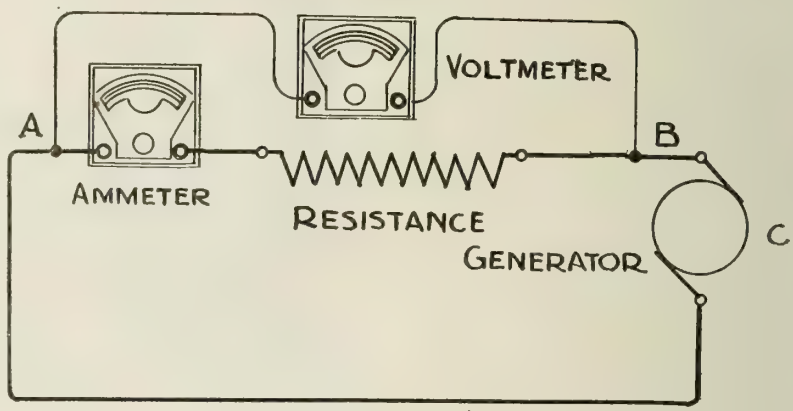

FIG. 2—METHOD OF MEASURING RESISTANCE.

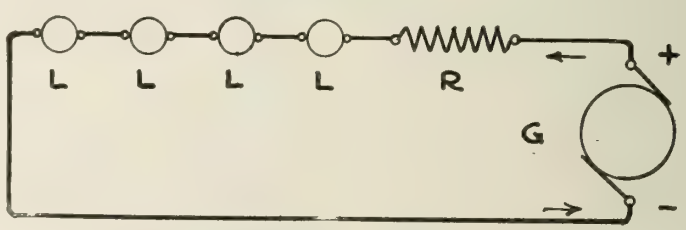

FIG. 3—EXAMPLE OF A SERIES CIRCUIT.

Various Forms of Ohm's Law

As will be gathered from the form of the equation and from the definitions of the quantities involved, Ohm's law enables any one of the three quantities to be found when the other two are known for:

$$R = \frac{E}{I} \text{ and } E = IR.$$

An example or two will serve to show how this law is used:

1—A dynamo having resistance of one ohm and an e.m.f of 150 volts has a lamp whose resistance is 24 ohms connected across its terminals. How much current flows through the circuit?

$$I = \frac{150}{I+24} = 6 \text{ amperes.}$$

In Fig. 1 is shown a circuit having a generator of a resistance of one ohm; a line each side of which is of 6 ohms resistance, and a resistance or other device having a resistance of 8 ohms.

If the generator has an e. m. f. of 147 volts the current flowing will be:

$$I = \frac{147}{21} = 7 \text{ amperes.}$$

If instead of the e. m. f. in Fig. I

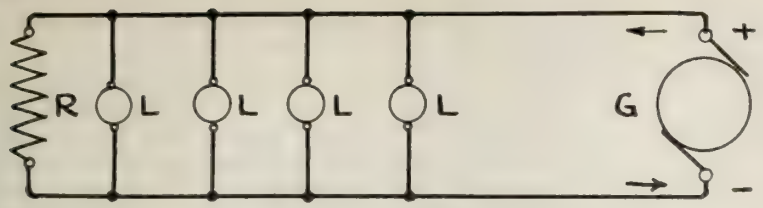

FIG. 4—EXAMPLE OF A MULTIPLE CIRCUIT.

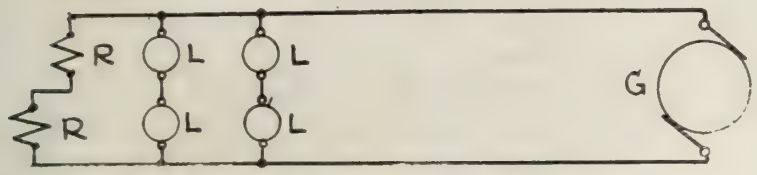

FIG. 5—EXAMPLE OF A SERIES MULTIPLE CIRCUIT.

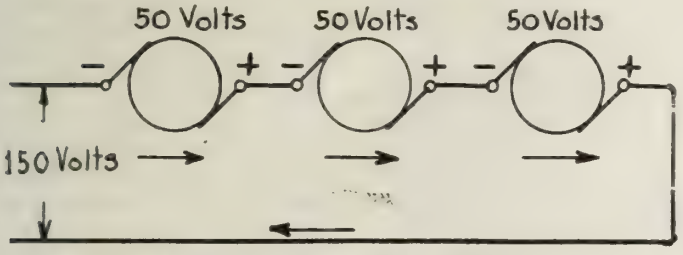

FIG. 6—3 GENERATORS IN SERIES.

being known, a current of 14 amperes is flowing and it is desired to find the voltage or e. m. f., one of the other forms of the equation may be used;

$E = IR$ or $E = 14 \times 21 = 294$ volts.

Ohm's Law Applied to Part of a Circuit

As has been explained it is the electromotive-force or e. m. f. that causes current to flow, and each part of the circuit depending upon its resistance requires a definite portion of the total e. m. f. to drive the current through it. This causes a difference of potential across the ends of the portion of the circuit considered.

In Fig. 2 is shown a circuit composed of a dynamo and a resistance with a voltmeter connected across the ends of the resistance. When the generator is running and delivering power the voltmeter will show a reading and the ammeter also shown in the circuit, will indicate the number of amperes flowing.

To the reading of the voltmeter is given the name potential difference, abbreviated p. d. This term has a slightly different meaning from e. m. f., which latter is usually used in the sense of measuring the voltage across the terminals of a generator or other apparatus when the circuit is open and no current flowing, while the term p. d. is usually applied to a portion only of the circuit.

Ohm's law holds equally good for any part of a circuit and it is not necessary to consider the whole circuit when applying it. The circuit shown in Fig. 2 is an example of this use of Ohm's law and is frequently used in the determining of resistance.

If a current of 10 amperes is flowing through the resistance and the voltmeter indicates a difference of potential of, for example, 15 volts, the resistance may readily be calculated;

$$R = \frac{E}{I} \text{ or } R = \frac{15}{10} = 1.5 \text{ ohms.}$$

Ohm's law for part of a circuit may be stated thus:

The amount of current in amperes flowing through any device in an electric circuit is equal to the fall of potential in volts through the device, divided by the resistance in ohms or $I = E \div R$, which is the same equation as before.

Circuits

A circuit is a path composed of a conductor or of several conductors joined together, through which an electric current flows and a circuit is said to be broken or opened when its conducting elements are disconnected in such a manner as to prevent the current from flowing. It is said to be completed or closed when its conducting elements are so connected as to allow a current to pass.

A circuit is said to be grounded when one of the conductors has been placed in contact with the ground either accidentally or by design. It is possible to use the earth as a conductor and thus dispense with one wire as is done in telegraphy and to a certain extent in street railway work.

The rails are used in street railway work as the return conductor and stray currents traversing the ground give considerable trouble in cities by causing electrolytic action, destroying water pipes, etc.

Series and Parallel Circuits

Conductors are said to be connected in series when they are joined so that the entire current must pass through each conductor or piece of apparatus successively.

Fig. 3 represents a simple series circuit in which all the current must pass through the resistance R and the lamps L before returning to the generator.

Fig. 4 represents a parallel or multiple circuit in wich the current flows through each of the lamps and the resistance, each one taking only a portion

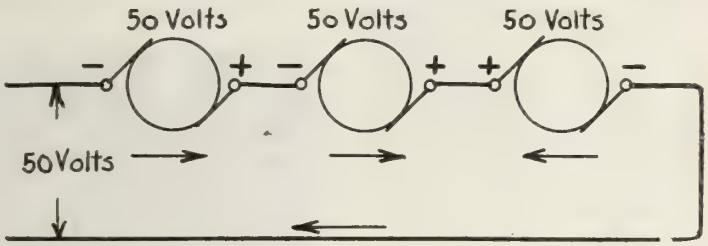

FIG. 7—THREE GENERATORS IN SERIES ONE OF WHICH IS OPPOSING THE OTHER TWO.

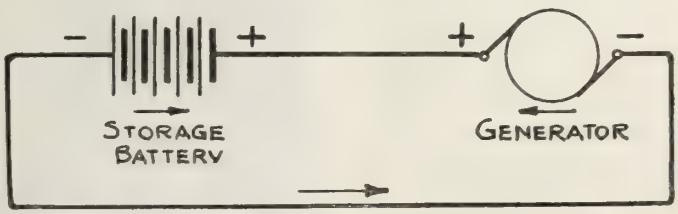

FIG. 8—ELEMENTARY BATTERY CHARGING DIAGRAM.

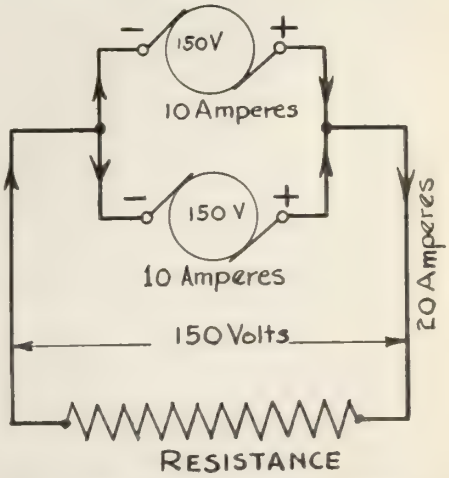

FIG. 9—TWO GENERATORS IN PARALLEL OR MULTIPLE.

of te total current. The term multiple is more frequently used than parallel.

Fig. 5 represents a series multiple circuit in which the current while having two or more paths open to it must still flow in series through the lamps or other apparatus forming one branch.

E. M. F.'s in Series and Parallel

More than one e. m. f. or source of current may act to send current through a circuit and like lamps or other apparatus they may be connected in either series or parallel. If connected in series they may all act to send the current the same way or one or more may tend to cause the current to flow in a direction opposed to the others. Thus in Fig. 6 the generators are all connected in such a manner that they all tend to cause the current to flow the same way and the total voltage or e. m. f. will be the sum of all three or 150 volts if each generator has an e. m. f. of 50 volts. In Fig. 7 one of the generators opposes the others and the resultant voltage is 50 + 50—50=50 volts. A common case of this latter connection is seen when a storage battery is charged as shown in elementary form in Fig. 8. In this case the positive terminal of the battery is connected to the positive terminal of the generator and it is due to the higher voltage of the generator that current flows into the battery when it is being charged.

That part of the e. m. f. which tends to send the current the other way in the circuit or which opposes the stronger e. m. f. is called the counter e. m. f. and the circuit acts as if there were no more voltage present than that due to the difference between the stronger and the weaker electro-motive forces.

If sources of current are connected in parallel they must have the same value or e. m. f. and be connected in the same way or otherwise considerable complexity will result. Fig. 9 shows two dynamos connected together each delivering 150 volts. The voltage in this circuit is simply that due to one machine, but the additional machine has provided a means such that the current in the main circuit comes from two sources instead of one.

Generators are connected in either series or parallel groupings, depending upon the characteristics of the lines and apparatus to which they deliver power. If the line is long and of consilerable resistance it is preferable to employ a series connection. This is very seldom done in direct current work, the more usual case being that of parallel grouping which while leaving the voltage unaltered delivers a greatly increased current depending upon the number of machines.

Answers to Last Month's Problems

A.—Electrical pressure or potential can exist without the flow of current, i.e., when a generator is running and the line switches are open.

B.—The names voltage, potential and electro-motive force are given to that property of an electric circuit which causes or tends to cause a current to flow.

C.—The unit of potential is the volt.

D.—The ampere is the name given to the electrical unit denoting rate of flow.

E.—The coulomb is the unit of quantity measurement of electricity.

F.—A motor running for 2 hours and taking a current of 50 amperes will absorb $50 \times 2 \times 60 \times 60 = 360{,}000$ coulombs or 100 ampere hours.

G.—The unit in which resistance is measured is termed the ohm.

This Month's Problems

1. What current is produced through a resistance of 5 ohms by an electro-motive force of 10 volts?

2. Through what resistance will an electro-motive force of 15 volts produce a current of 3 amperes?

3. What electro motive-force will produce a current of 4 amperes through a resistance of 4 ohms?

4. A dynamo generates 500 volts; the resistance of the circuit including the dynamo is 20 ohms. What is the current?

5. What electro motive force must a dynamo generate to supply an electro-plating current of 20 amperes through a circuit whose total resistance is .2 ohm?

6. An electric bell has a resistance of 400 ohms and will not ring with a current of less than .03 ampere. Neglecting the resistance of the battery and line, what is the smallest electro-motive force that will ring the bell?

7. If a car heater is supplied with an electro-motive force of 500 volts from the trolley, how great must be its resistance if the current is not to exceed 5 amperes?

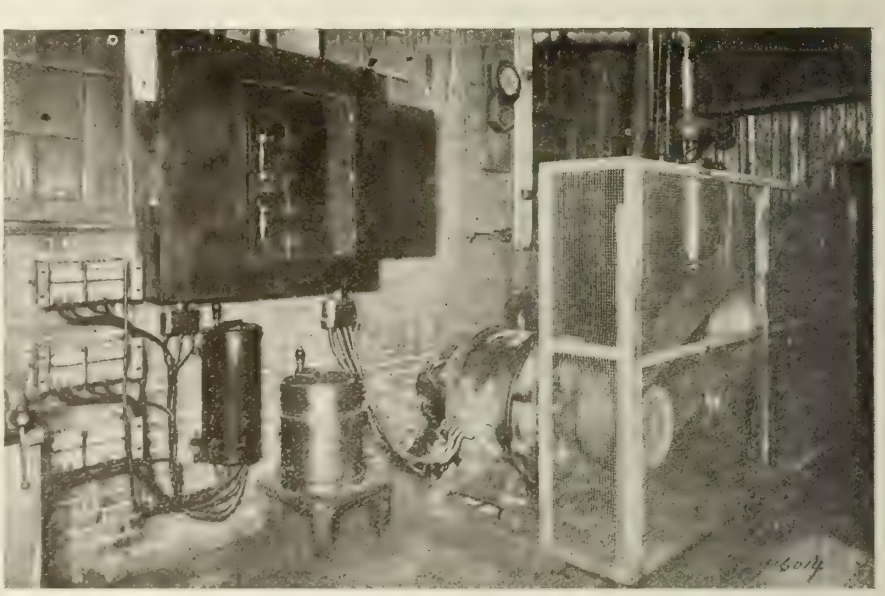
8. Calculate the resistance of the resistance R shown in Fig. 9, assuming as in the diagram that the electro-motive force is 150 volts, the current flowing is 25 amperes and the internal resistance of the dynamo is one ohm. Note: Neglect the resistance of the line in this problem; find the total resistance, and then deduct the generator resistance.

ELECTRIC DRIVE SAVES THIRTY PER CENT.

THE electric motor shown in the accompanying engraving is one of several aggregating 150 horsepower which replaced a steam engine for power purposes in an iron foundry effecting a saving of thirty per cent. in power cost.

The motor shown in the illustration is a 50 h.p. machine and drives a 12-in. by 12-in. Curtis air compressor. This motor is of the wound-rotor type, desirable for compressor service because its field is adjustable. At the left of the compressor motor is seen its controller, that for another motor, and above, Krantz safety-type switches for each motor. These are so arranged that it is impossible to get at any part of the circuit while it is alive. The fuse compartment cannot be unlocked until the switch is open.

In addition to the saving in power-cost, the management finds the power supply of central station lines to be more steady and satisfactory than that of their own power plant. This leaves all their energies free for the main job, turning out sound castings on schedule time and at a minimum cost.



ARRANGEMENT OF 50 HORSE-POWER MOTOR WITH CONTROLLER AND SAFETY SWITCHES.

IT is customary to determine roughly the excess air in boiler furnaces by the per cent. of CO_2 in the flue gases. As a matter of fact, the CO_2 is not an immediate measure except in rare cases, but the practice has grown because it is easy to determine the CO_2, and comparatively difficult to determine the real excess air. Assuming complete combustion, the per cent. of CO_2 is an indirect measure of the excess air used; but in even that case it varies for each different kind of fuel. For example, in the case of fuel oil, 8 per cent. CO_2 would mean about 96 per cent. excess air, while in the case of soft coal it would mean about 125 per cent. excess air.

Switch Gear Standardization: Necessity and Advantages

By C. C. Garrard

The problem of the standardization of equipment is receiving world-wide attention and it is a well-recognized fact that if a country wishes to maintain its position in the engineering markets of the future standardization of equipment will become necessary.

OF all departments of electrical engineering, switch-gear is perhaps the one whose development is in the greatest state of flux and in which more changes and improvements are continually taking place, and will continue to take place, than in any other. Under these circumstances, at first sight, it may be thought that it is a very unfit subject for standardization. Such a conclusion, however, betrays a want of appreciation of the true and best meaning of standardization. Standardization properly understood is essentially a co-operative action on the part of the designers and manufacturers concerned in order that the best product may be produced in the shortest time and with the least expenditure. To attain this end each party throws into the common stock his knowledge and experience; the old-fashioned secretive policy is abandoned, it being recognized that in this, as in so many other departments of national life, the purely individualistic policy must give way to the more enlightened and, in the long run, better paying one of mutual help and combined action.

In a paper read before the Institution of Electrical Engineers, the author summarizes the work which has been done in the past and gives a resumé of the lines along which the standardization of switch gear may be expected to proceed in the future.

The authority for engineering standardization in Great Britain is the Engineering Standards Committee. According to the 1917 report of the committee no single standard specification dealing with any form of switchgear has been issued. Specifications dealing with wall plugs and ceiling roses have, it is true, been prepared, but these come under the domain of accessories and not that of switchgear properly understood. In fact there does not seem to be any suitable organization within the standards committee to deal with such work. There is a sub-committee, with a number of panels for dealing with electrical accessories. But heavy modern switchgear is not properly classed under this designation. It would appear that there is urgent need for the formation of a special sub-committee to deal specifically with switch and controlling gear. This sub-committee could arrange for its special panels for the various subjects and there need be very little, if any, overlapping of the existing electrical accessories sub-committee and panels.

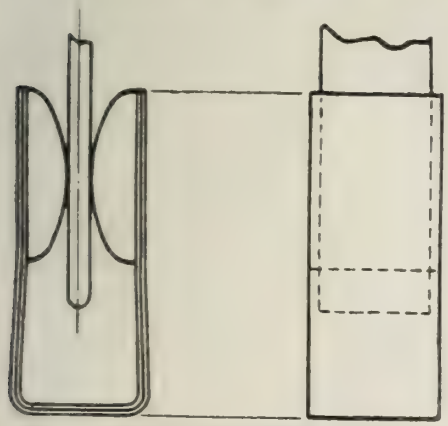


FIG. 1—CONTROLLER-FINGER TYPE OF SWITCH CONTACT.

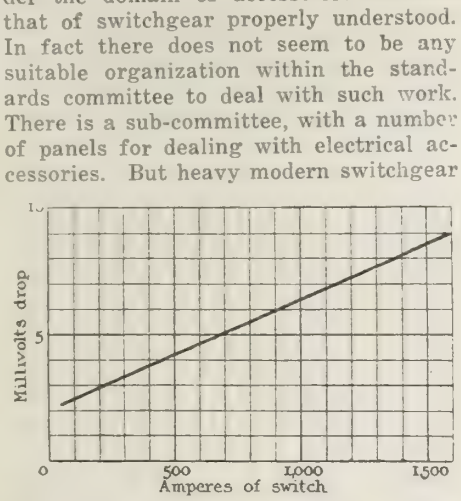

FIG. 2—MILLI-VOLT DROP AT THE JAWS OF KNIFE SWITCHES.

In the following remarks it is desired to explore to some extent the ground indicated, and to discuss a number of matters in connection therewith.

Standard Test Voltage for Switchgear

In the various specifications being issued by the engineering standards committee test voltage are enumerated for the articles dealt with. It would, however, be better if a standard test voltage could be agreed upon applicable to all switch and controlling gear. This should be higher than the corresponding test for machinery. The American standardization rule No. 500 specifies for machinery a test pressure equal to 1,000 volts plus twice the normal; for switches and control apparatus above 600 volts, however, rule No. 509 calls for 2,000 volts plus 2¼ times the rated voltage. This latter test is very good and reasonable, and moreover is a sufficiently high one for any form of switchgear. We cannot do better than adopt it.

Conductivity of Current-Carrying Alloys

The standardization of copper has already received considerable attention from the engineering standards committee, and a similar standardization of the other current-carrying materials used in switchgear should be made. These include brass, gunmetal and phosphor bronze. In passing, it may be mentioned that the whole subject of copper alloys stands in urgent need of standardization. The percentage composition of a "brass" casting is, for example, a very nebulous quantity. Even the standard specification (No. 35), which gives the standard dimensions for brass rods is but little used by the trade. There is no doubt but that electrical engineers, in common with all other users of brass, would heartily welcome standardization along the lines indicated. The following specification for brass castings which has been used in want of a better one may be of interest:—

Specification for Brass and Gunmetal for Castings

Brass.—Castings must be clean and free from sand and without fins, gits, or blow-holes. No trace of iron or nickel must be present. The composition should be within the following limits:—

Copper, 66 to 75 per cent.
Remainder zinc, impurities not to exceed 2 per cent. of total weight.

Gunmetal.—Must be of similar general quality to the brass above specified. Particular care must be given to freedom from blow-holes in order to secure good electrical conductivity. Composition:—

Copper	88 to 90	per cent.
Tin	10 to 11	"
Zinc	1 to 2	"

Knife Switches

A standardization of the length of break, distance between the centre lines of the poles, sizes of terminals, current density in the material and general style of construction is very necessary. At the present time various authorities have fixed their own standards, necessitating special manufacture. In addition, numbers of obsolete requirements are still insisted upon in certain quarters. For example, the condition that the hinge of

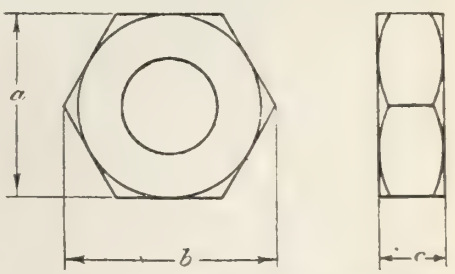

FIG. 3—SWITCHBOARD CONNECTION NUTS. Faces are to be dead true and smooth as they are for surface contacts.

a knife switch should not carry current still survives. This should be obviated in future. As regards the current density of surface contacts, it is not desirable to fix limits as to this, as apparently very high surface densities sometimes

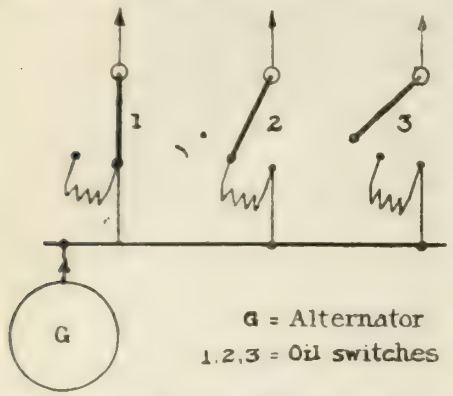

FIG. 4—DIAGRAM ILLUSTRATING THE USE OF TWO STEP OIL SWITCHES HAVING RESISTANCES, OR CHOKING COILS, CONNECTED BETWEEN THE STEPS.

yield very good results. There is much to be said in favor of the type of switch contact illustrated in Fig. 1.

The explanation would appear to be that with the ordinary form of flat contact the current really only passes at a single or a few points. With the controller-finger type, however, a definite line contact is obtained. A standardization of the millivolt drop, at contacts however, would be a very good thing, and, as this is a direct measurement of the capability of the device to make contact, has much to recommend it. The values given in Fig. 2 are founded on actual practice in good class work.

Current-Carrying Back Connection Studs for Switches, Etc.

Considerable variations exist at present in the practice of different manufacturers in regard to back connection studs, more especially as regards the screw threads adopted. The type of thread used must be determined more from considerations of electrical conductivity than from mechanical ones. The Whitworth screw threads, for example, on the larger sizes have too coarse a pitch which cuts unduly into the cross-section of the rod. A standardization of these screw threads, as also of the corresponding nuts, is very necessary. The particulars given in Table 1 have been found suitable by the author and are put forward as a basis of discussion. It will be seen that with the exception of the smallest size the Whitworth form of thread has been adhered to. In all sizes, however, above ⅝ inch diameter the pitch is smaller than that of the corresponding diameter Whitworth standard screw. It would not be desirable to standardize studs above 3,000 amperes. For these very large sizes the laminated construction is to be preferred. Strip connections are riveted and soldered into the switch block. These constitute a better electrical connection and, moreover, are cheaper to construct in these sizes than studs would be.

TABLE I.

Suggested Standards for Back Connection Studs for Switches, etc.

Current in Amperes	Rod Diameter of Studs in inches	Screwing of Stud
3,000	2	11 threads per inch, Whitworth-shaped thread
2,500	1¾	" " "
2,000	1⅝	" " "
1,800	1½	" " "
1,500	1⅜	" " "
1,200	1¼	" " "
1,000	1⅛	" " "
800	1	" " "
600	⅞	" " "
400	¾	" " "
300	⅝	⅝ in. Whitworth standard 11 threads per inch
200	½	½ in. " 12 "
150	7-16	7-16 in. " 14 "
100	⅜	⅜ in. " 16 "
75	5-16	5-16 in. " 18 "
50	¼	¼ in. " 20 "
25	0.184 to 0.186	No. 2 B.A.

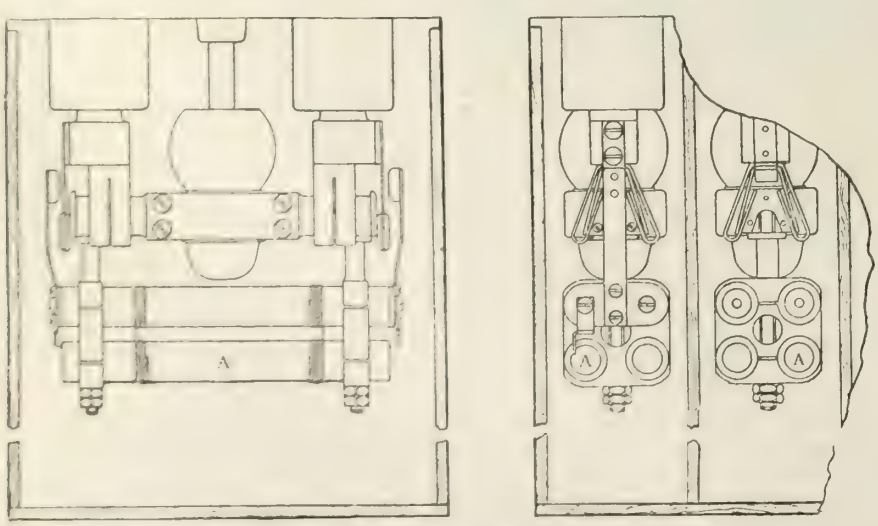

FIG. 5—OIL-SWITCH WITH SELF CONTAINED CHARGING RESISTANCE.
A = charging resistance.

Connection Nuts

The nuts for making the connection between the studs and the connection strips must be thinner than standard Whitworth nuts. This is necessary in the first place from considerations of space, which is naturally limited at the back of switchboards. The chief point, however, is that it must be possible to make a neat job of the multiple strip connections attached to the studs so arranged that they occupy the minimum of space consistent with efficient ventilation. The best arrangement is to make the spacing nuts double the thickness of the standard connection strip.

The nuts should be practically flat sided, the corners only being slightly chamfered to prevent their cutting into the material of the strips.

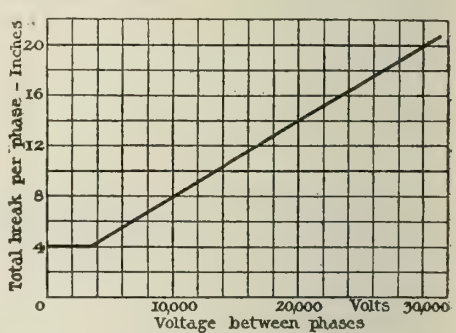

FIG. 6—CURVE CONNECTING TOTAL LENGTH OF BREAK AND VOLTAGE OF OIL SWITCHES.

Oil Switches

The standardization of oil switches is at the moment receiving attention and will therefore not be discussed at great length here. It will, however, not be out of place to call attention to the considerable amount of work which has taken place in other countries. This has had the result, before the war, of greatly assisting our foreign competitors' export trade in switchgear.

The action of heavy-duty oil switches is still really very little understood. The buyer, therefore, in choosing which switch to purchase is greatly influenced by the opinion he holds of the technical knowledge of the manufacturer offering the goods. The German manufacturer, for example, fortified with a set of carefully worked-out standards, was at a great advantage as compared with the British manufacturer who had nothing similar to put forward. Happily we are within measureable distance of an alteration of this state of affairs.

The German rules referred to not only include a set of standards as regards the construction of the switches themselves, but also a number of suggestions to guide the operating engineer in his

selection of a suitable switch having regard to the possible value of the short-circuit current at the situation where the switch is to be used. Such a set of rules is of the utmost service.

Referring again to the switches themselves, the most important point in their standardization is that of their rating in terms of breaking capacity. It is obvious that such a rating can only be reliable if based upon actual experience. It must be confessed that many of the ratings of oil switches which are guaranteed by various manufacturers are merely intelligent guesses, as means for making such tests are as a rule not available. In the appendix will be found references to a number of such tests which have been published. The opportunities for making such tests in this country are, however, very few. The engineers in charge of our large supply undertakings are naturally chary of undertaking the not negligible risks entailed in such tests. Yet such systematic tests are necessary if progress is to be made in a reasonable time. In this connection it is noteworthy

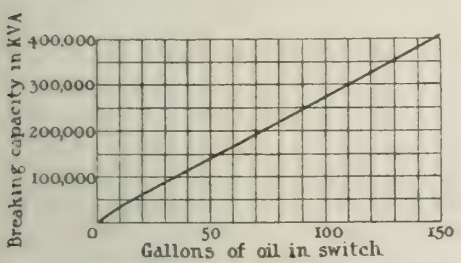

FIG. 7—CURVE CONNECTING QUANTITY OF OIL AND BREAKING CAPACITY OF OIL CIRCUIT BREAKERS.

that recently, and since the war, the Allgemeine Electricitats Gesellschaft of Berlin has built a special laboratory for the specific purpose of testing oil switches. This has been described recently in the technical press; it is worthy of the attention of the institution that, while last year the British Government, through he Department for Scientific and Industrial Research, encouraged an investigation in the subject of switching and arcing to the extent of a few hundred pounds, at precisely the same time this Berlin firm was building a special laboratory for exactly the same research at a cost probably one hundred times as great.

The question will be asked: Can this handicap under which we are suffering be removed? If left to the individual firms it is improbable that any single concern will go to the great expense of establishing and running a research laboratory on the necessary large scale. Moreover, to the author it appears that this would be much better dealt with by co-operative action between the industry as a whole and the government. This action could take the form of the establishment of a national high-tension research and standardizing laboratory which could deal with such problems as this and those mentioned under the heading of lighting arresters. The equipment, staffing, and running of an efficient laboratory on the necessary scale mean something altogether different from anything yet attempted in this country. The very best engineering talent should be secured for its direction and considerable financial resources would have to be available for the large scale experiments necessary.

Breaking Capacity of an Oil Switch

The leading consideration to be borne in mind when installing an oil switch on a large system is the maximum power in kilovolt-amperes which it will have to rupture. On large modern plants this power becomes very large and there can be little doubt that to some extent the value of short-circuit has increased more quickly than the corresponding improvements in the oil-switch construction. The use of reactances to limit the short-circuit current has now become recognized as essential for continuity of supply and it is of interest to discuss the conditions imposed upon such sectionalizing of large systems by the present state of development of the oil switch. While it is no doubt possible to construct oil switches for any duty whatsoever yet if too great a demand be made upon them they become so large and unwieldy that it is better to adopt other means of limiting the short-circuit current and thus enabling the relatively smaller switches to be used. It is suggested, therefore, that a maximum breaking capacity of 500,000 k.v.a. should be regarded, at any rate with the present state of the art, as the largest short-circuit load with which any oil switch should be called upon to deal.

The standard rules when formulated should embrace sizes up to this value.

Resistance and Reactance Type Oil Circuit-Breakers

The use of the two-step oil switch (Fig. 4), having a resistance or choking coil connected between the two steps has been advocated in some quarters. The Swiss Elektrotechnischer Verein in its report recommends this. With such a switch, on switching in, the resistance is momentarily connected in series with the circuit and then short-circuited. On switching off the order of procedure is reversed; Fig. 5 is a drawing of such a switch. As such arrangements considerably increase the complexity of the oil switches it is very desirable to elicit expression of opinion as to the advantages of the system and as to whether any standard specification should contain any provision for such an arrangement. Such switches may be regarded from two points of view, that is to say, switching-on and switching off.

Switching-on of Two-Step Oil Switches

The use of the charging resistance is of value in the case of switching-in of large transformers, for preventing the abnormal rush of current which sometimes occurs. Such a current, however, lasts only for a very short time, and the only real trouble is due to the tripping of the overload release gear. This can be guarded against by a time lag on the transformer switch. For switching-in cables such double-contact switches are totally unnecessary.

Such charging resistances are also sometimes called for for switching in large motors, the object being to prevent the concentration of voltage across the end turns of the windings and consequent danger of internal short-circuit. For this purpose a non-inductive resistance is not much good but a charging choke coil should be used. It must be admitted, however, that a method such as this is simply a condonation of inferior insulation of the machine concerned. If this latter were properly constructed, such special switching appliances should not be necessary. If, however, some such safeguard is deemed to be unavoidable, then a small adequately insulated, choke coil permanently in circuit with the machine may be used.

Switching-off of Two-Step Oil Switches

The Swiss Electrotechnical Society base their recommendation of the use of such double-contact switches on their alleged capability of dealing with heavier short-circuits than single-contact switches. It is very much to be doubted whether this contention is right, and in the absence of reliable test results, made under the heaviest conditions, it should not be accepted.

To the present author the great objection to such switches is their complexity. An oil switch in a large system is subjected to such severe usage that it should be constructed in the strongest and simplest manner with as few parts to get out of order as possible. From this point of view the use of double contact switches should be discouraged.

It is possible, by means of special constructions, to shorten considerably the length of break necessary in an oil switch. As, however, these devices come under the destructive effect of the arc every time the switch operates, it would seem a dangerous policy wholly to rely upon them.

It is better to have such a length of break that a reasonable degree of safety is secured, even if the special devices mentioned are put out of action. By length of break is meant the total length; thus if there are two breaks per phase it is the sum of the two breaks. Fig. 6 represents the average of a number of first-class modern manufacturers and may be taken as typical of present-day designs. For switches of exceptionally large breaking capacity, however, the breaks are sometimes larger than those indicated in the curve.

Single and Multiple Tanks on Oil Switches

There is an impression in some quarters that the mere division of an oil-switch tank into three separate tanks, one for each phase, is an advantage from

the point of view of operation under short-circuit. Seeing, however, that the effect of this sub-division is to bring earthed metal betwen the phases and in closer proximity to the contacts, the effect is likely to be the other way about. Of course in all cases for switches of any considerable size, insulating barriers should be arranged between the phases. The question as to whether a separate oil tank should be used per phase is simply, in the first instance, one of size and weight. On the larger switches a single tank becomes too unwieldy to handle. For great breaking capacities, therefore, three tanks are used, and with such switches it is better to arrange for actual concrete or brick barriers to separate the phases entirely.

Amount of Oil Required for Oil Switches

Very considerable variations have existed in the practice of the various manufacturers as regards the quantity of oil deemed necessary for a switch of given breaking capacity. As, however, the oil is the medium for taking up the energy liberated within the switch at the instant of rupture, it is to be assumed, from first principles, that the more oil there is the greater the breaking capacity, provided, of course, that the whole of the oil is brought into effective use. This view is gradually becoming general and much larger oil tanks than were previously used are now common. The curve in Fig. 7 connects the total quantity of oil and maximum k.v.a. breaking capacity, and may be taken as representing good modern practice.

Speed of Operation of Oil Circuit-breakers

A high speed of operation is now recognized as an important factor in increasing the breaking capacity. There are two points to be considered; first, the total time required for the travel of the switch from the instant that the contacts finally part company to the completion of the travel; secondly, the initial speed at which the break contacts separate. The second is the more important, as it is of the utmost importance that the current be finally ruptured during as small a proportion of the total travel as possible. Information regarding these two points should be sufficient to define the action of the breaker in this respect. If by speed of operation is meant the actual velocity of the moving portion of the switch, it must be borne in mind that if there are two breaks per phase the circuit is being actually opened at twice the speed of the mechanism. This could be taken into account by multiplying the actual mechanical speed by the number of breaks per phase.

(To be continued.)

THE DISTILLATION OF COAL UNDER PRESSURE

IT is well recognized that, at the best, the burning of coal under ordinary conditions and manufacture of coke in the beehive oven are very wasteful. The valuable by-products derived from the coal under proper conditions are an exceedingly important factor in many industries.

In the ordinary destructive distillation of coal most of the volatile matter is driven out at 650 deg. C. and lower temperatures. To reach that temperature within the mass of coal, the retort is subjected to a temperature of nearly 1,000 deg. C. As a consequence, a considerable portion of the vapours generated is spontaneously cracked in the retort by remaining in contact with the hot retort walls and the hot coke. Satisfactory means of avoiding that cracking have not yet been developed; in other words, low-temperature carbonization is much written about, but hardly practised so far. It will require a great deal more experimenting before the problem will technically be solved. Distillation under reduced pressure has repeatedly been tried. Messrs. J. H. Capps and G. A. Hulett, of Princeton University, New Jersey, have recently been experimenting on the effects of higher pressures of 20 atmospheres. They find that the increased pressure favors the production of light oils at the expense of the heavier oils, but experiments on a small scale, such as they conducted, offer great analytical difficulties, and in any case a few such experiments hardly admit of any conclusions as to the economic balance of a process. The experiments, described in the "Journal of Industrial and Engineering Chemistry," of October 1, 1917, pages 927 to 935, were made with a steel retort of 1.9 litres capacity. The apparatus resembled a mercury thermometer with a long vertical bulb, into the stem of which a vertical cooling tube had been axially inserted. The heavy vapors rising from the coal were condensed on this internal tube and dripped back into the retort. If the stem had been cooled from the outside the vapors would have run down the inside of the retort wall, where they would have been overheated and have deposited a crust of coke, insulating the coal from the hot walls. The steel retort was wound with asbestos and nichrome tape for electric heating, and the temperature was raised to 600 deg. C. in the start at the rate of about 5 deg. per minute, and then at the rate of 1 deg. per minute. A tube branching off from the stem took the vapors first to a trap condenser and then through a horizontal tube, cooled from outside, to a second condenser and to the apparatus for analyzing and measuring the gases and vapors. The first trap was a vertical cylinder, the vertical axis of which was taken up by a cooling tube; in cross-section this trap was U-shaped; the trap and part of the retort stem were surrounded by a case which was electrically heated so as to prevent the condensation of the low-boiling oils in this first condenser. Thus a rough distinction between heavy and light vapors was rendered possible. The retort, stem and the first trap were made sufficiently strong to bear an internal pressure of 20 atmospheres, which was measured by a gauge. The temperature inside the retort was indicated by a thermocouple. Four kinds of coal were examined, a steam coal from Virginia, a bituminous coal from Pittsburgh, an Illinois soft coal, and a sub-bituminous coal from Wyoming; if we remember rightly these coals have served for several researches conducted by the Bureau of Mines, in conjunction with which Capps and Hulett were working. The general results are that as the pressure was increased, more of the heavy hydrocarbons were decomposed, while up to 5 per cent. more light oils or products of lower boiling-points appeared in the second condenser ;the phenols and acids likewise decreased for reasons which are not clear. At higher pressure more coke was produced, but the calorific value of this coke was increased, the coke being more free from nitrogen, oxygen, sulphur and volatile matter than under ordinary conditions. The volume of non-condensable gas was also increased by the rise of pressure: up to 500 deg. C. more hydrogen was evolved, at 550 deg. and 600 deg. the hydrogen percentage diminished again, probably because the hydrogen then reacted with the nitrogen, oxygen and sulphur and some of the compounds.

ARMATURE BURNED OUT

By M. L.

The cores of generators and motor armatures are built up of soft steel sheet called laminations. This construction is used to reduce the local currents which would be considerable and cause excessive heating were the core solid. Breaking the continuity of the core with joints increases the resistance to eddy currents, but the resistance is further increased either by oxidising the laminations or by giving them a coat of Japan or insulating varnish.

That the object of the laminated construction sometimes may not be appreciated is illustrated by the following experience:—The armature of a large continuous-current generator burned out on account of a ground due to lightning. On removing the damaged coils, it was discovered that a large hole had been burned into the core. The operator, who evidently considered that local repairs might safely be made without regard to laminated construction, went to considerable expense to machine the whole affected part of the core and carefully to dovetail into a block of solid iron into which had been milled slots for the armature coils. The armature was then rewound and replaced in commission, only to be burned out again in the same place after a brief operation.

The operator drew the correct conclusion as to the cause of the second failure; his second repair job was even more original than the first one and more effective. He removed the block of iron and inserted a wooden one. The coils then were repaired and replaced, and this makeshift construction proved to be satisfactory for the time being. Later, the only permanent method of making such a repair was adopted, that is, to remove the defective laminations and reassemble that part of the core with new ones.

Steam and Its Generation

CONSERVATION OF FUEL

By H. James

THE fuel controller has ordered that the Canadian factories economize. This means that all intelligent people are wondering where it will all end and at the same time these people are doing everything they can in their own homes to try and save coal. It is not a question of how many tons can be saved but of how many shovelfuls each individual householder can conserve. A few small details such as keeping the building at a temperature just warm enough and no warmer, say 65 degrees Fah., which will be suffcient, and will result in better health. Double windows, etc., can be fitted better and the furnace fittings can be made tighter and the pipes insulated, while the flues and chimneys should be kept clean.

Are the manufacturers paying as much attention to details as they might?

It seems that there are many ways of effecting economies such as selecting the firemen with a view of obtaining conscientious, intelligent men who will follow instructions and not fire irregularly —light and heavy—and who will distribute the coal evenly. Railway officials, who have spent considerable time on the general fuel situation have found that firing a boiler is a job which requires intelligence if the maximum efficiency is to be maintained because, at best, burning coal is wasteful. The boiler settings should be checked, the draft and grate area considered and the flues should be thoroughly cleaned and made free from scale without waiting for the boiler inspector to come around as these details are just as important as shovelling in the coal. How many of the manufacturers have been asked by the fuel controller to have these details attended to? Not very many. It is not the average householder who is wasteful but it is the factories and hotels.

Plant Economies

It is a good idea to have a recording thermometer showing the room temperatures at all times and it will be noticed how soon the firemen will become interested and the fuel consumption will drop. Conditions have existed where a recording thermometer reduced the fuel consumption over 30 per cent., and this plant was an average factory. It should be borne in mind that sudden changes in the firing should not be made if the maximum results are to be obtained but any changes should be foreseen and gradually made.

Formerly it was possible to specify the brand of coal and to see that the quality was kept up by checking the various ingredients but now the consumer is obliged to take anything he can get, with the result that there is little economy obtained from selecting the different grades.

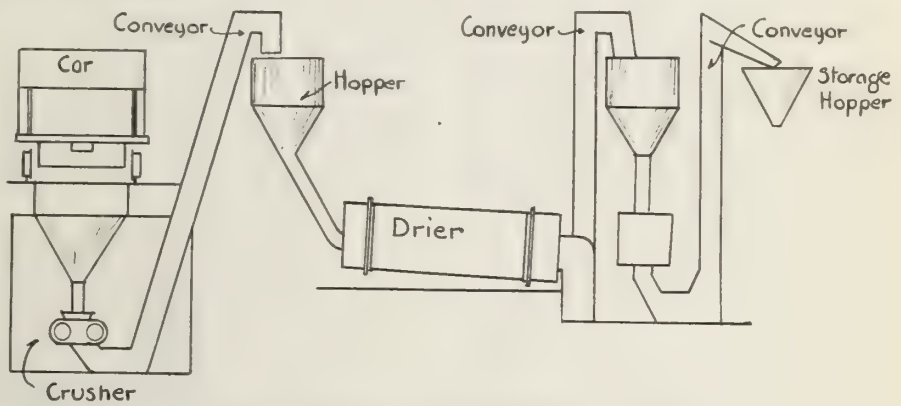
For the small plant, fuel oil is probably cheaper as it possible to control the heat with such ease that slight variations in atmospheric temperature can be allowed for and advantage taken of the mild spells by shutting down periodically or altogether. This flexibility or operation has made it possible to effect considerable saving and on account of the possibility of regulating the fuel and air with precision more perfect combustion is obtained.

The first cost of the oil compares favorably with the increased price of coal, and actual results have shown it is preferable for the small plant. No very radical changes are necessary to alter the equipment except in the drafts and brick work. The only change to the grates is the reducing of the volume of air coming down through by making a checker work of brick. A little experimenting with the different types of furnaces will very easily establish the correct area of combustion chamber, etc. The extra cost for piping tanks, etc., is quite within reason.

Powdered Coal

The use of powdered coal has many advantages over the ordinary method of burning coal and is far more economical as every particle of coal is surrounded with the necessary amount of air to insure complete combustion.

Formerly the specifications for the quality of the coal to be used in pulverizing coal plants were rather exacting but up-to-date practice shows that if due care is given to the operation of a powdered coal plant quite a lot of latitude may be given and the results will not be impaired. Coal containing 28 per cent. volatile combustible matter is being used successfully and even poorer grades may be used. Except in the case of open hearth, puddling of bushelling furnaces, where the composition of the material being worked would be affected



COAL HANDLING AND PULVERIZING PLANT.

sulphur is of little importance, and even in these cases it is a debatable point as to whether the composition would be affected enough to matter. Moisture is absorbed very rapidly by powdered coal; it may amount to 0.01 per cent. per minute for a definite period, after which the absorption rate will diminish. Like fuel oil, if the air is preheated to say 500 degrees Fah., a saving of 20 per cent. may be effected. A simple way of accomplishing this is to pass a few lengths of blast pipe through a chamber heated by waste gases. The feed control and burner sizes are important factors in burning powdered coal. A few typical analyses of coal used in the powdered form are given:

	%	%	%
Volatile combustible matter	33.2	23.55	35.50
Fixed carbon	56.07	67.3	55.15
Water	1.12	0.35	0.40
Ash	9.61	8.08	8.95
Sulphur	1.00	2.04	1.51

An idea of what a pulverized coal plant is like may be gained from the accompanying illustration which shows a permanent installation.

The total equipment necessary for pulverizing, handling, drying and milling 2½ tons per hour, which is sufficient

for five forge furnaces, would cost around $60,000.

Equipment Necessary

The coal is dumped from the car into a steel car hopper located at the end of the milling building and in a concrete pit under the track. The hopper is made of ⅜-inch steel plates, and is 8x8x6 ft. deep, with sides sloping to a square opening where the feeding conveyor is located. A slide gate can be used to control the feed. The conveyor is a 6-inch standard horizontal, U shape, and conveys the coal from the hopper to the milling room. A crusher 20 x 24 in., with two cast iron toothed rolls is capable of crushing lumps from 8 inches to a suitable size for the pulverizer, which is about ¾ inch. The rolls are provided with a spring release in case some foreign substance should get into the crusher. From the crusher there is a boot-legged conveyor to the crushed coal bin. This conveyor is of the bucket type with 35 ft. centers and is covered to make it dust proof.

An arrangement is provided to distribute the coal uniformly in the coal bin which has a capacity of 60 tons and is reinforced 5-16 in. steel plates. The bottom is hoppered and arranged to connect to a conveyor which feeds the drier. The drier should be in a separate building on account of the liability of explosions. The drier reduces the moisture from 7½ per cent. to 1 per cent. It is composed of two shells made of heavy steel plate and having butt joints with inside lapping strips. The outer shell rotates at a speed of 6 r.p.m. and the inner shell connects with the furnace, the hot gases passing through it and at the end are carried away by a fan. The discharge goes to a dust collector which catches the finely divided particles of coal taken up during the passage through the drier. The shell of the drier is 48 in. x 20 ft. long, supported by rollers operated by spur gearing. The whole is placed at an angle and the outer shell contains helical vanes which convey the coal from one end to the other. At the firing end grate bars and ash pit doors for hand firing are arranged. The combustion chamber is lined with fire brick as is also the steel flue which connects with the drier shell.

The exhauster is belt-driven and of the centrifugal type. Provision can be made to deflect the hot gases from the drier when it is not in use by providing an auxiliary pipe connected to the fire box. The dust collector can be of the cyclone type. From the drier the coal is taken to a bin which is connected to the pulverizing mill by a conveyor. A 33-inch belt-driven vertical type with automatic feed and with a screen separator will take care of 2½ tons per hour. The pulverized coal is conveyed to a storage. Coal is taken as required to the furnaces by screw conveyors which lubricate themselves with the coal.

It is important that the pulverizing be fine enough so that the product will have at least 90 to 95 per cent. passing through a 100 mesh sieve. A relatively small air pressure is used by most people, this varies from 1 to 6 ounces, but some use as high as 10 to 15 ounces and have the mixture rotated in a mixing drum which tends to make a more thorough mixture instead of throwing the suspended coal across the furnace, and in some cases having it unburned. Some concerns use slack coal, and by first passing over a trommel the large material is segregated and the small coal sent to the pulverizer. The large coal is sent to the power house and consumed.

MODERN COOLING TOWERS

By Frank C. Perkins

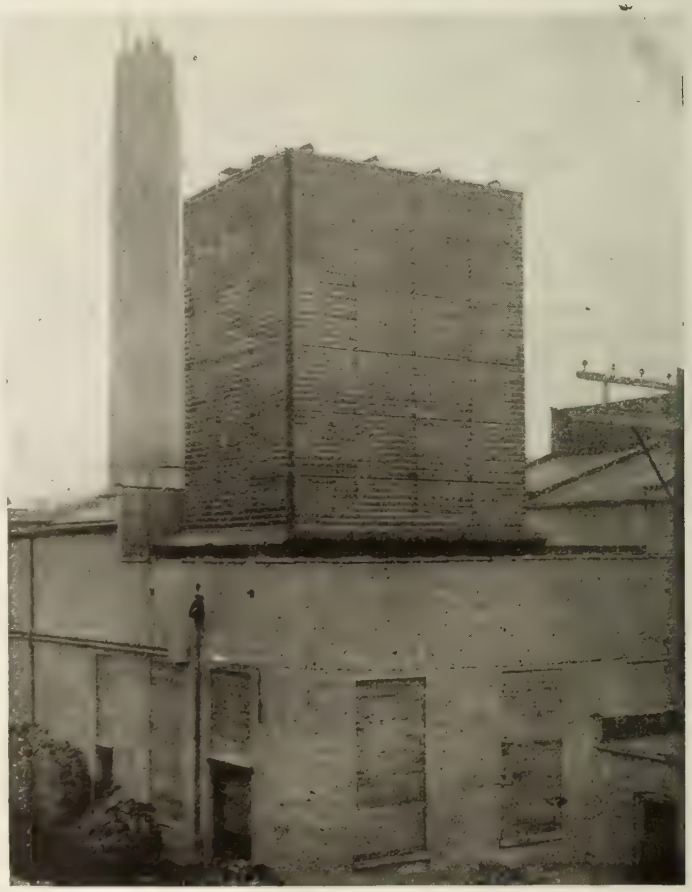
THE accompanying illustration shows a modern cooling tower in use, as developed by Engineer Edwin Burhorn.

In the construction of these cooling towers, a distributing device is placed at the top of the tower. A main trough is provided in the centre of the tower, and running nearly the full length of the tower on its longest dimension. At right angles to the main trough and extending at both sides of the trough are a series of distributing troughs into which the water from the main trough discharges.

It may be stated that the main trough consists of a steel box divided into two parts by means of a longitudinal partition. The water enters at either end through a tapped flange. One of these ends is to be plugged and will serve in cleaning out the lower compartment. A series of vertical pipes is furnished in the partition, and the water issues from these pipes, which are adjustable, so that the amount can be regulated to distribute uniformly throughout the length of the trough. The two sides of the trough are notched at intervals. through these notches the water overflows into the distributing troughs.

It is of interest to note that the main trough is made of heavy steel plate and thoroughly painted at the shop before shipment. A steel walk-way is provided running the full length of the tower alongside of the main trough, giving access to the regulating pipes in the main trough, and to all portions of the tower at the top. A steel ladder is provided to give access to the walk-way from the base of the tower.. The distributing troughs are notched on the sides the full length, at intervals, and the water overflows through these notches to the trough deck below.

A trough deck system of cooling surface is made up of units of proper size and placed side by side so as to give the proper area to suit the capacity of the tower. Each unit consists of a series of parallel troughs notched on the two sides. These parallel troughs rest on a similar series of parallel angle pieces running at right angles and bolted together with ⅜-inch bolts and double washers. The angle pieces stiffen the troughs so that they will maintain their level when full of water, and will also bear the weight of a man without deflection. The various units are bolted to channel iron beams by means of cast iron clips and through bolts, thus requiring no punching of the steel framework. The trough deck system erected level will cause the water to seek its level in the



A MODERN COOLING TOWER CONSTRUCTED OF STEEL PLATE.

troughs regardless of how it enters the troughs from above, and the water being level, will naturally leave the troughs through the notches throughout its entire length uniformly. The water from each notch will strike the top of the supporting angle at the centre and will tend to flow down both sides of the angle pieces in equal proportion. The arrangement of troughs and angle pieces at right angles will prevent water from passing directly through, but will enable a free passage of air up and around all parts of the angles and the troughs, thus exposing the water to the air under favorable conditions.

Arrangement of Troughs

It will be seen that the trough decks are arranged in series one directly below the other. The troughs in one deck are arranged to run at right angles to those in the deck above and below. This method will rectify the distribution of the water from deck to deck, as the tendency of the wind is to blow the water to the leeward side of the tower. Without such rectification, the water concentrates at the leeward side of the tower and, at the bottom of the tower, will splash in considerable volume. This will result in poor cooling effect and considerable loss of water by splashing out of the tower. With the trough deck system the distribution is equalized at each deck so that no matter in which direction the wind may blow, the water is always broken up into fine particles, and exposes the maximum water surface to the surrounding air.

It is pointed out that in the operation of a cooling tower the same water is used over and over again. Through the process of cooling there is a certain loss which must be made up from some outside source. This loss is known as the "Make-up Water," and consists of water lost by evaporation plus water that might be splashed or blown out of the cooling tower. Assuming that there is no less except that due to evaporation, the amount of heat (in British Thermal units) taken away from the water in circulation will equal the number of pounds of water lost, multiplied by approximately 1,000. In other words, every pound of water evaporated will carry away one thousand heat units, and cool one thousand pounds of water one degree, or one hundred pounds of water ten degrees. Therefore, to cool one hundred pounds of water ten degrees requires the evaporation of one pound of water, or 1 per cent. of the amount cooled. Thus, theoretically, the make-up water will be 1 per cent. of the water circulated, to cool the water 10 degrees.

It is said that actual tests on several towers under different conditions have shown the actual loss to be less than 1½ per cent. of the total amount circulated, or practically that due to evaporation. The design of the trough deck system, combined with the louvres, prevents water blowing out of the tower, even in heavy winds, and thus only are we able to accomplish the above mentioned remarkable result.

It is maintained that the distributing and trough deck system described hereinbefore is entirely free from perforations, and has no parts liable to clog up, so that the tower is suitable for any kind of water, and will require practically no attention after once properly adjusted. Experience has demonstrated the desirability and durability of all steel construction. On account of the presence of acid in the water at various locations, due to the character of the water itself in some cases, and in others to the accumulation of acid from smoke in the atmosphere, which latter often contains sulphuric acid, we protect the trough deck system by a thorough dipping in protective compound. The individual parts are made of galvanized material, and after completion are thoroughly dipped in a protective compound, which latter is a special mixture suitable for the purpose.

It is said that where local conditions call for any special material or treatment, a careful study should be made and the proper method adopted. The louvres are ordinarily made of galvanized metal. In certain cases the louvres and trough decks are made of commercially pure copper at some extra cost, and in other cases are made of black steel galvanized by the hot dipping process, which gives a very heavy coating and adds considerably to the durability under bad local conditions. This hot dipping also adds to the cost of the tower.

READER'S QUERY

MY practice lies chiefly in the line of agricultural engines and steam plants of the smaller capacity, these engines, or rather the boilers, are not under government supervision, and a large majority of them are old and nearly all, especially those in localities where the water is charged with minerals, are more or less attacked by scale and corrosion which nearly always leads to pitting and the formation of pin head.

I have read a good deal of technical matter regarding the prevention of scale in boilers, and the principal causes of its formation; some builders advocate the use of kerosene when laying up a boiler, others say that oil of any kind should never enter a boiler. Of course kerosene is supposed to be free from the more dangerous acids, and for that reason some engineers in this branch of the profession use it when laying up a boiler to prevent deterioration and corrosion.

I would like to have the following questions answered:

(1) Do you consider the hydraulic boiler test reliable? It is probably so for the boiler as a whole, and if there is any danger of failure due to fracture of the sheets it will show up under the hydrostatic pressure, but probably the boiler is full of pit holes, not close enough to be dangerous, yet so thin as to be liable to burst at any time. I have placed a boiler under the test myself and found that everything seemed to be all right, yet a short time after a burst occurred. I would like to know if a boiler more or less afflicted with pit holes is actually dangerous.

(2) When laying up a boiler for a few months how should one proceed? I do not refer to large stationery boilers, that is a comparatively easy matter, as a man can enter these boilers, but with the small internally-fired boilers a man must proceed without any knowledge of the boiler's condition.

(3) I suppose no oil except the kerosene should be used unless it is known to be free from acid, and the boiler should be thoroughly boiled out with soda before being put into service again. Is this correct?

(4) Could kerosene be used in connection with the purger on an injector to feed through to the boiler with the feed water?

(5) Is it possible for one to test a small boiler with a light hammer and be able to locate weak places and pit holes, or can this test be considered reliable in the hand of one not accustomed to the different sounds?

(6) What sound should a boiler give out when in good condition, also what would be the indications of weak or worn and corroded places?

(7) What effect has age on the boiler plates provided they have escaped the effects of scale and corrosion; is it possible that the alternate contraction and expansion has the effect of producing structural changes

Forest, Ont. Roy J. Brodie.

Answer

(1) In the writer's opinion the hydrostatic test alone is not reliable, but after the boiler has been thoroughly inspected, internally and externally and the plates hammered with a test hammer to locate thinning, slack stays, broken screw stays, etc., the hydrostatic test with slightly warm water is very useful in summing up as it enables the inspector to locate and have leaks stopped up in the seams, tubes, etc. By careful inspection it can be determined if the straps are properly spaced to support the flat surfaces of thin plates and by this method plates which have been thinned through corrosion or which have had screw stays broken may deflect on test.

(2) When laying up a portable boiler for the winter the handholes should be opened up and all scale scraped out, using a hose with nozzle pressure to wash out the loose scale. After the scale has been disposed of and the hand hole covers replaced the boiler should be filled up and two gallons of kerosene oil poured in. The exact amount of oil depends to a large extent upon the size of the boiler. The blow-off should next be opened and the boiler allowed to empty slowly; this will distribute the oil in a thin film on the inside surfaces and preserve them from the action of the lying up period. If the boiler lies for six months the oil will have evaporated by the time the boiler is put into service and any slight residue will not

matter. Externally the plates should be scraped clean and painted with graphite paint to preserve them.

(3) Yes, and refer to question 2.

(4) Keep all oil out of boilers under operation, oil is dangerous.

(5) Yes, in the hands of an experienced man the test hammer is invaluable for testing boilers.

(6) The sound given out by a hammer in testing plates that are of full thickness is well known to competent inspectors, and an experienced man testing boilers can immediately tell when he comes to thin spots as these give out a different sound of a tinny nature. Weak, worn and corroded places are observed by this means.

(7) The plates in a boiler which has been in constant use for a large number of years undergo a gradual change, becoming less ductile and being "crystallized in service." This is due to the expansion and contraction of the plates in service.

CAUSES OF CHIMNEY TROUBLES

By C. T.

QUITE recently a contractor having trouble with a steam plant invited an examination of the conditions existing by twelve individuals who seemed to have the necessary experience to find out the cause of the trouble, and whilst no two of them agreed each claimed to be confident of the solution of the problem. Among the opinions expressed were that the coal was poor, that the smoke flue was too long, that the chimney flue was not large enough, that it was too large, that it was due to the smoke flue not running upgrade, that it was due to two fires running into one flue, and finally the manufacturers of the steam boiler sent a representative who declared that he would stake his twenty years' experience that the trouble was due to the chimney not being high enough, although it was one foot higher than the peak of the roof. After all this the builder himself discovered that the trouble was caused by an eddy of cold air at the base of the chimney flue. The various wrong opinions were expressed by plumbers, steam fitters, masons and others who should have been able to explain such troubles promptly.

Few people seem to have any definite idea of what the actual troubles in a chimney may be, for there are at least fourteen definite kinds which all manufacturers and steam users should be familiar with and able to detect on sight.

1. The flue may be too small for the work put upon it.

2. The flue may be too large, and therefore the heat not sufficient to cause proper draught. These two troubles can be easily detected by consulting a table of flue sizes in most furnace catalogues.

3. Leaks where outside chimneys join the foundation walls. This condition may be easily traced by watching a lighted candle near the junction point. An inward current will indicate such a leak.

4. Leaks between flue linings and the brick walls of the chimney.

5. Flue joints not set flush. These conditions should be prevented by the inspection of the work as it progresses, and in the case of a straight chimney they can be detected by holding a pocket mirror in the base of the chimney at an angle that will reveal the sky above the chimney top, the entire interior of the chimney being easily visible.

6. The top opening of the chimney may be too small. It is too small if smaller than the balance of the chimney. It is best to finish with a flue lining larger than those below.

7. The top of the chimney may be too low. It must be one foot higher than the roof, at least, unless 20 feet away.

8. The flue lining should be a little higher than the brick wall, and if lower it may cause trouble.

9. Aviators complain of "air pockets." These will spoil the draft of chimneys located next to higher buildings.

10. High trees adjoining will cause similar difficulty.

11. Sharp bends in a chimney can cause trouble by creating eddies and by reducing the capacity of the chimney.

12. A depression or well beneath the flue opening can cause an eddy that will be almost fatal to chimney draught.

13. When a rather small flue pipe enters the base of a chimney a little larger than the capacity required a cold air eddy may exist, due to the cold air settling down one side of the flue, while the hot gases pass up the other side. This can be cured by reducing the size of the flue as it approaches the base.

14. If the smoke flue does not fit airtight all the way into the inner flue lining there will always be trouble. There is especially a chance of leakage between the lining and the brick in this case.

A UNIQUE ELECTRIC COAL CONVEYOR

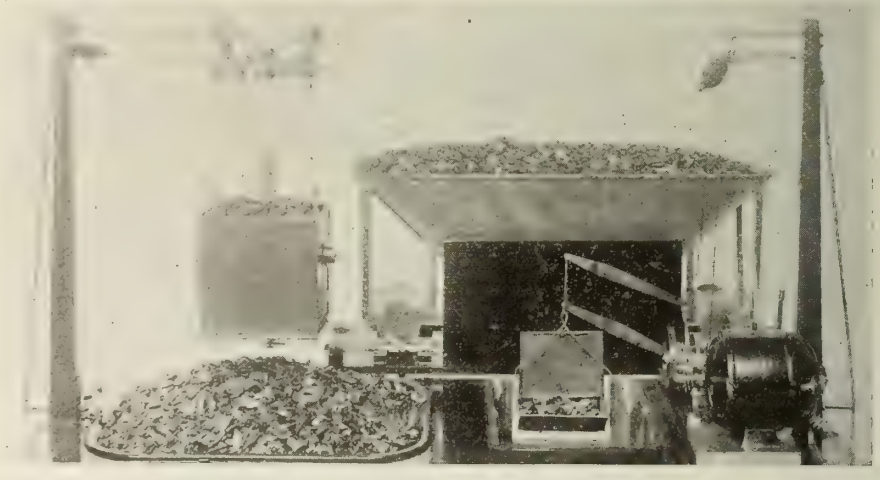
By E. R. K.

THE accompanying illustration shows a model of a new coal conveyor system which is said to be a great improvement in coal unloading and storage methods as developed at Elkhart, Indiana.

This method was devised to handle the unloading and storage of coal for the retail coal dealer, just as mines are employing modern methods in putting coal into the cars.

The conveyor is entirely mechanical and reduces labor by eliminating hand shoveling. One man operator only is necessary and it reduces breakage and degradation by not dropping, dragging, scraping or squeezing the coal, successfully handling all sizes. It increases the storage capacity by filling the bins to the roof with no limit as to height and uses gasoline or electric power for its operation.

This reversible overhead conveyor is provided with a self-dumping and self-closing bucket of thirty-six cubic feet capacity. The railroad track hopper is equipped with a single action, double gate with apron attachment. One operator at the hoist can control the entire operation, lower the bucket any distance from the operator, raise it again and return it to its starting point. A large spring inside the bucket is so placed as to let the coal out by gravity and close again when bucket is empty. The bucket is lowered from overhead car down to the pile and automatically dumped, allowing the coal to pass out without dropping as soon as the bucket is raised. As soon as the tripper comes in contact with the coal the safety device is unhooked, and as the bucket shifts on the suspending ropes this allows the tripper to slide off the bottom and the weight of the contents of the bucket forces the door open.



WORKING MODEL OF UNIQUE COAL HANDLING OUTFIT ADAPTED FOR THE SMALL DEALER.

At the Elkhart installation the bucket used is of 1-ton capacity. The coal is dropped into a pit at the side of the railroad track and filled from a chute which receives the coal from the hopper bottom of the coal car. The bucket is hauled up an incline track, being supplied with trunnion rollers at each side which operate upon the track, and is lowered upon the top of the pile or bin. A trigger releases the bottom of the bucket and the weight of the coal causes the bucket to empty, when the spring bottom immediately closes and is ready

for another load. In order to get the bucket back to the starting point a double drum arrangement and a double pulley on the carrier are used. This device has a capacity of unloading about three cars in eight hours, or ample capacity for the average coal dealer. One of the advantages of this plan is that the coal is not broken up and a second advantage is that nothing like the initial investment cost of a typical coal elevator is required.

HOW TO USE A PSYCHROMETRIC CHART

By J. I. Lyle

IN all branches of engineering requiring more than the ordinary amount of calculation, it has been the tendency to simplify the various computations, as far as possible, by the use of tables or charts, or both. In the field of thermodynamics no one subject has been in greater need of such simplification than air conditioning. Here we have a variety of problems in which a slight alteration of the conditions often makes an astonishing difference in the total results.

Since the development of air conditioning on its present extensive scale it has become a matter of the first importance for heating engineers to familiarize themselves with the principles involved. Up to the present time it is a matter of common knowledge that the average heating engineer has not brushed up on this subject to the extent he should in order to take advantage of his growing opportunities in this field.

Among the various noteworthy psychrometric charts that have been published is one designed by Willis H. Carrier and presented in a paper read before the American Society of Mechanical Engineers. This chart was acclaimed at the time as a classic of its kind and it immediately took rank as an authoritative exposition of the subject. Recently a new form of this chart has appeared, which is reproduced herewith.

It is generally recognized that much time and labor may be saved by the use of this and similar charts, but the fact remains that such saving depends to a very large extent on how familiar one becomes with the chart itself. In short, it is often true that while the advantages of a given chart are freely admitted, the time required to master its use often acts as a deterrent to its widespread adoption.

In an effort to remove this possibility, as far as this particular chart is concerned, the following instructions have been prepared, in which almost every feature of an air conditioning problem has been presented and its solution shown on the chart.

Instructions For Use of Chart

All references to temperature are in degrees Fahrenheit.

Dry-bulb temperatures are represented by vertical lines, with values indicated on lower edge of chart.

Wet-bulb temperatures are represented by oblique straight lines, with values indicated on curved line marked "wet bulb temperature."

Dew-point temperatures are represented by horizontal lines and their values indicated on curved lines marked "wet-bulb temperature."

Percentages of relative humidity are represented by converging curved lines, with values indicated between the oblique straight lines for 63° and 64° wet-bulb temperature.

Any two of the above properties may be found if the other two are known. First, find the point of intersection of the lines representing the given properties, and then follow through this point, the lines representing the unknown properties, and the values of the latter can be read from their respective scales.

Example 1.—Given: Dry-bulb temperature, 70°; wet-bulb temperature 60°. Find the percentage of relative humidity and the dew point. Locate point of intersection of vertical line representing 70° dry-bulb temperature and the oblique line representing 60° wet-bulb temperature.

Reading from this point the percentage of relative humidity is 56 and the dew-point 53.4°.

Example 2.—Given: Dry-bulb temperature, 80°; relative humidity, 59%. Find the dew-point and wet-bulb temperature. Locate the point of intersection of the vertical line representing 80° dry-bulb temperature and the curved line representing 59% humidity.

Reading from this point, the dew-point is 64.8° and the wet-bulb temperature 69.5°.

Example 3. Given: Dry-bulb temperature, 75°; dew-point temperature, 55°. Find percentage of relative humidity and wet-bulb temperature. Locate the point of intersection of the vertical line representing 75° dry-bulb temperature and the horizontal line representing 55° (wet-bulb scale).

Reading from this point the relative humidity is 49.8% and the wet-bulb temperature 62.3°.

Example 4. Given: relative humidity. 50%; wet-bulb temperature, 60°. Find dry-bulb temperature and dew-point. Locate the point of intersection of the curved line representing 50% humidity and the oblique line representing 60° wet-bulb temperature.

Reading from this point. the dry-bulb temperature is 71.7° and the dew point 52°.

Example 5. Given: wet-bulb temperature, 55°; dew-point, 50°. Find dry-bulb temperature and relative humidity. Locate the point of intersection of the oblique line representing 50° wet-bulb temperature and the horizontal line representing dew-point of 50°.

Reading from this point the dry-bulb temperature is 61.5° and the relative humidity 68%.

Example 6. Given: Relative humidity, 40%; dew-point, 40°. Find dry-bulb temperature and wet-bulb temperature. Locate the point of intersection of the curved line representing 40% relative humidity and the horizontal line representing 40° dew point.

Reading from this point, the dry-bulb temperature is 65.02° and the wet-bulb temperature 52°.

Total Heat of Air

The total heat of air is a function of its wet-bulb temperature, as described and proven by Willis H. Carrier in his rational psychrometric formulae. In the chart, it is taken for the sake of convenience as above zero, degrees Fahrenheit.

The total heat in B. T. U. is represented by horizontal lines with values indicated at the left by the scale D, "Total Heat Above Zero Degrees contained in One Pound of Dry Air Saturated with Moisture."

To find the total heat, the wet-bulb temperature must first be determined. Then follow the vertical line through the wet-bulb temperature reading at 100% humidity, to the "Total Heat" curve D. The horizontal line through this point represents the total heat above zero, and the value is indicated on the scale D at the left.

Example 7. Given: Dry-bulb temperature, 70°; relative humidity 60%. Find the total heat. The wet-bulb temperature determined by the method used in Example 2, is 61°. Following the vertical line through the point representing 61° wet-bulb temperature and 100% relative humidity, to its intersection with curve D and then reading horizontally to scale D on the left, the total heat above zero degrees in one pound of given air is 26.7 B. T. U. The total heat to be removed in cooling air between two temperatures is found by substracting the total heat at the lower temperature from that at the upper as follows:

33.5 B.T.U.,	Total heat above zero degrees (dry bulb 70°)
26.7 B.T.U.,	Total heat above zero degrees (wet bulb 61°)
6.8 B.T.U.	Heat to be removed by cooling.

Absolute Humidity (Grains of Moisture Per Cubic Foot)

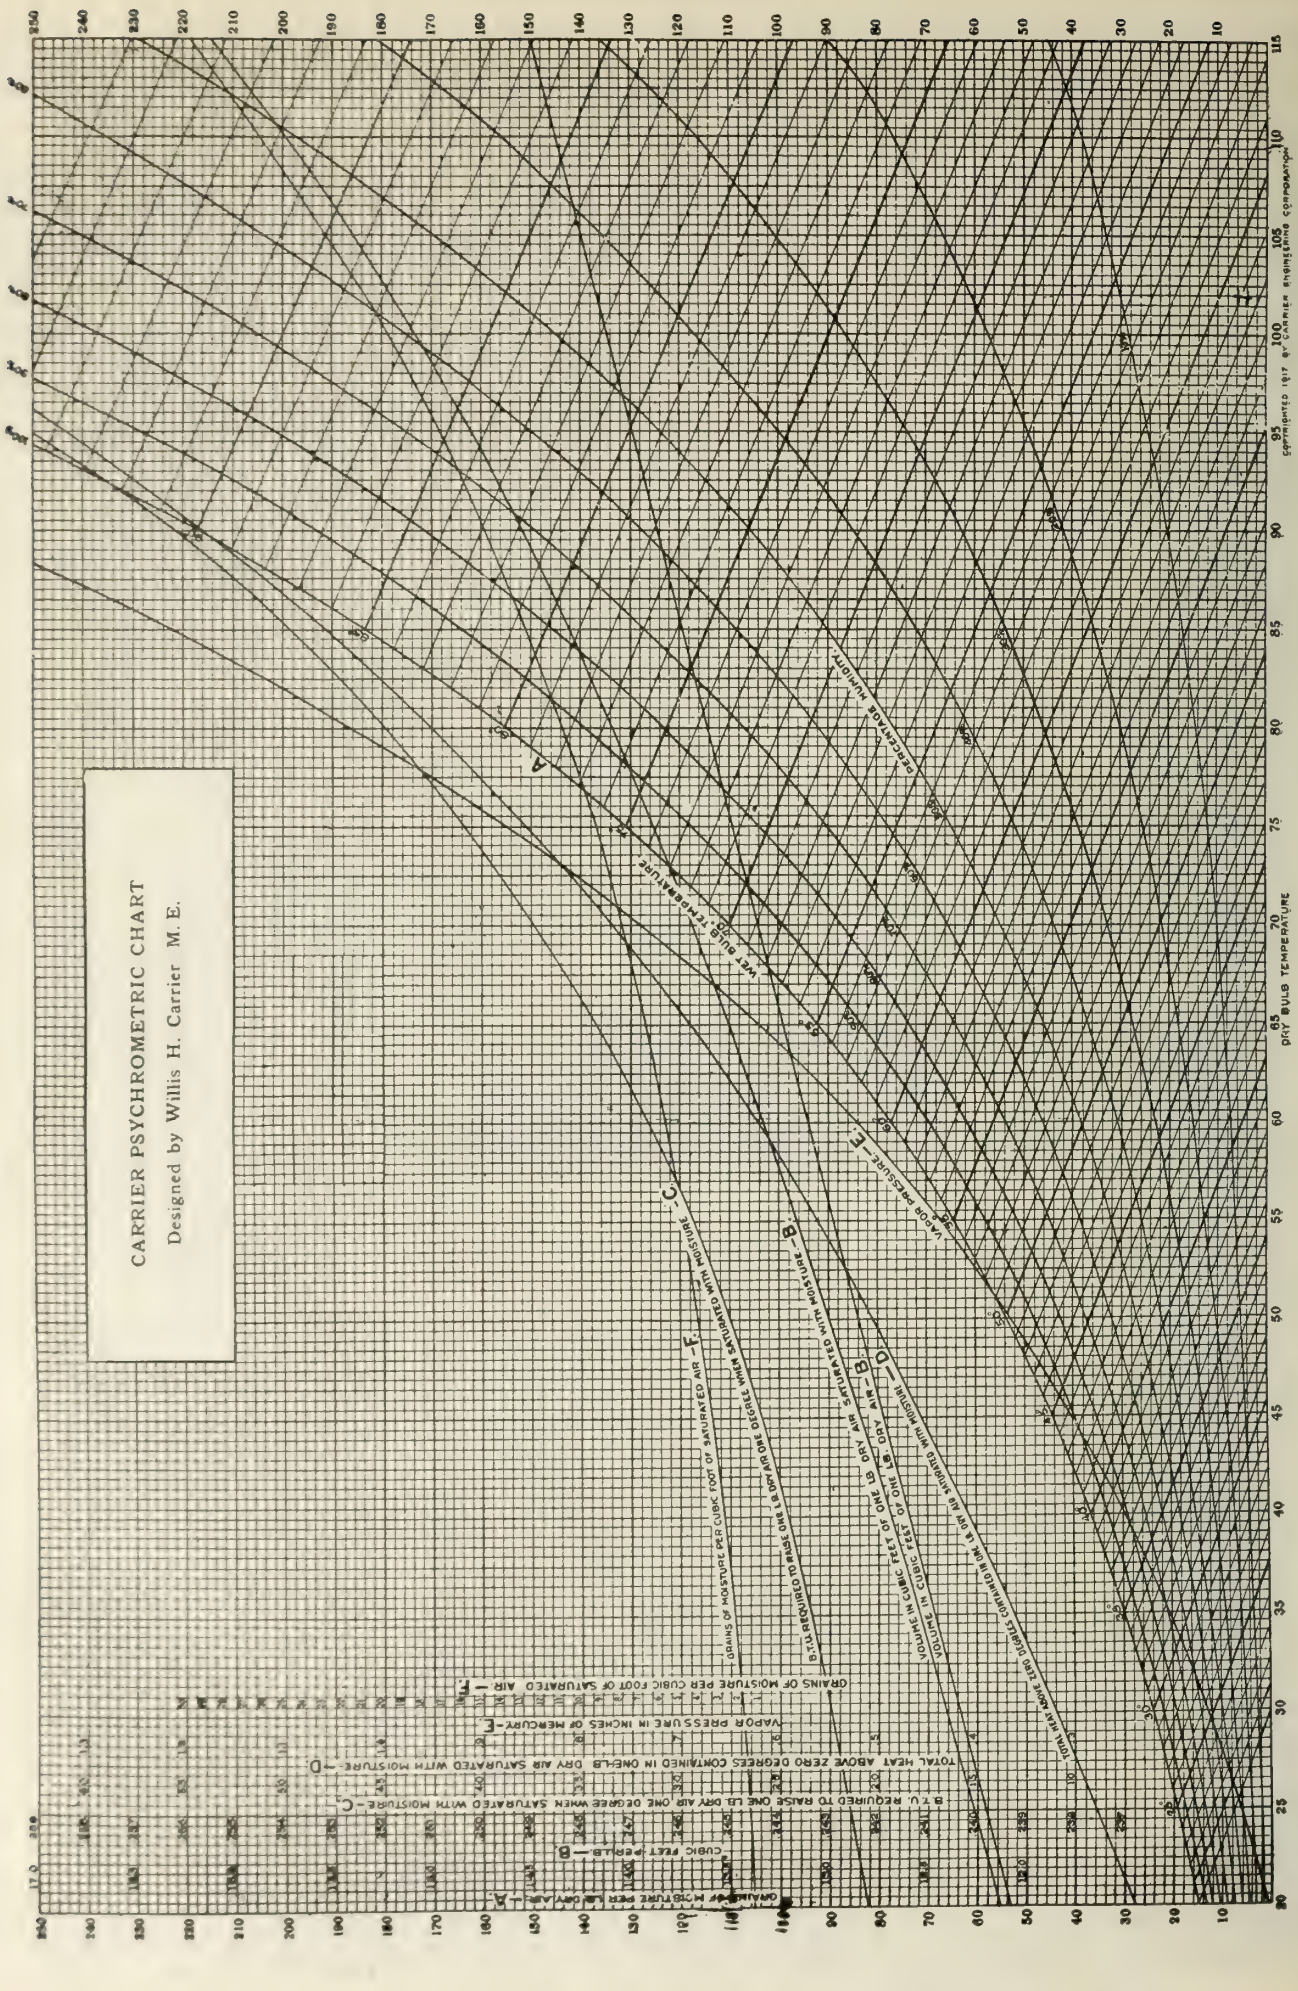
Absolute humidity is a function of the dew-point and may be expressed either ingrains per pound or dry air or in grains per cubic foot.

The grains of moisture per pound of dry air are represented by horizontal lines with values indicated on the scale A, "Grains of Moisture per Pound of Dry Air."

To find the grains of moisture per cubic foot for air under given conditions, first determine the grains per pound of dry air by finding the intersection of the (vertical) dry-bulb line and the (oblique) wet-bulb line and reading from there horizontally to scale A, "Grains of Moisture per Pound of Dry Air" at the left.

The volume in cubic feet per pound of dry air is represented by horizontal lines with values indicated by scale B, "Cubic Feet per Pound."

Find the points of intersection of the (vertical) dry-bulb temperature line with the curves B, "Volume in Cubic Feet of One Pound of Dry Air Saturated with Moisture" and "Volume in Cubic Feet of



CARRIER PSYCHROMETRIC CHART
Designed by Willis H. Carrier M. E.
DRY BULB TEMPERATURE
WET BULB TEMPERATURE
PERCENTAGE HUMIDITY
VAPOR PRESSURE
GRAINS OF MOISTURE PER LB. OF DRY AIR
CUBIC FEET PER LB.
B.T.U. REQUIRED TO RAISE ONE LB. DRY AIR ONE DEGREE WHEN SATURATED WITH MOISTURE
TOTAL HEAT ABOVE ZERO DEGREES CONTAINED IN ONE LB. DRY AIR SATURATED WITH MOISTURE
VAPOR PRESSURE IN INCHES OF MERCURY
GRAINS OF MOISTURE PER CUBIC FOOT OF SATURATED AIR
GRAINS OF MOISTURE PER CUBIC FOOT OF SATURATED AIR
B.T.U. REQUIRED TO RAISE ONE LB DRY AIR ONE DEGREE WHEN SATURATED WITH MOISTURE
VOLUME IN CUBIC FEET OF ONE LB. OF DRY AIR AND IT'S ASSOCIATED MOISTURE
TOTAL HEAT ABOVE ZERO DEGREES CONTAINED IN ONE LB. DRY AIR AND IT'S ASSOCIATED MOISTURE
COPYRIGHTED 1917 BY CARRIER ENGINEERING CORPORATION

One Pound of Dry Air." Follow these horizontally to the left and read the values on scale B. The difference in these two readings of volumes is the extra volume due to moisture at 100% humidity.

To obtain the direct volume of the moisture per pound of air under the given conditions, find the volume of water vapor for the given per cent. of humidity and add it to the volume of dry air.

Then grains of moisture per cubic foot or in other words the absolute humidity, is

$$\frac{\text{Grains per pound of dry air}}{\text{Cubic feet per pound of mixture}}$$

Example 8. Given: Dry-bulb temperature, 70°; wet-bulb temperature, 60°. Find the absolute humidity (grains of moisture per cubic feet).

Reading vertically on the 70° dry-bulb line and obliquely on the 60° wet-bulb line to the curve marked "Wet-Bulb Temperature," and from there horizontally to Scale A, the number of grains of moisture per pound of dry air is 61.

Then locate the points of intersection of the vertical dry-bulb line for 70° with the two curves B, and follow these horizontally to scale B at the left.

13.7 cu. ft.—Volume of one pound of dry air saturated with moisture.

13.38 cu. ft.—Volume of one pound of dry air.

0.32 cu. ft.—Extra volume due to moisture at 100% humidity.

(In instances where the air is saturated or dry, its volume may be found directly by locating the point of intersection of the [vertical] dry bulb line with the corresponding curve B and referring to the scale B.)

The percentage of humidity for air under the given conditions is indicated where the 70° dry and 60° wet-bulb lines intersect, which by interpolating between the 60° and 50° humidity curves is 57%.

57% of 0.32 is 0.1824 cu. ft., volume of moisture in the given air.

13.38 cu. ft.—volume of dry air.

0.1824 cu. ft.—volume of moisture.

13.5624 cu. ft.—volume of one pound of the given mixture.

$$\frac{61 \text{ gr. per lb.}}{13{,}5624 \text{ gr. per cu. ft.}} = 4.499 \text{ grains of moisture per cubic foot.}$$

Vapor pressure in inches of mercury depends upon the dew point and is represented by horizontal lines with values indicated by the scale E "Vapor Pressure in Inches of Mercury."

To determine the vapor pressure, read horizontally from intersection of (vertical) dry-bulb line with (oblique) wet-bulb line. Read through the wet-bulb temperature scale A and the "Vapor Pressure" curve E to the scale E at the left. The reading here is the vapor pressure. It should be noted when getting the reading for saturated air that the dew-point, wet and dry-blub temperatures are identical.

Example 9. Given: dry-bulb temperature 70°; wet-bulb temperature, 60°. Find the vapour pressure.

Reading vertically on the 70° dry-bulb line to the point of intersection with the (oblique) 60° wet-bulb line, and then horizontally through the wet-bulb temperature curve A, through the dew point and (wet-bulb reading is 53.5°) to the vertical scale E, "Vapor Pressure in Inches of Mercury." The vapor pressure for this point reads 0.405 inches.

To Find the Resulting Relative Humidity When Heating or Cooling Air Without Changing its Dew Point

Find the dew-point line for the given conditions which is the horizontal line through the point of intersection of the (vertical) dry-bulb line with the (oblique) wet-bulb line. Follow this line horizontally to the new dry-bulb temperature line and read the percentage of humidity for this point of intersection.

Exampe 10. Given: dry-bulb temperature, 70°; wet-bulb temperature, 60°. Find the resulting relative humidity when the air is heated to 80° (dry-bulb temperature).

The point of intersection of (vertical) 70° dry-bulb and (oblique) 60° wet-bulb lines indicates an existing humidity of 56%. Following the point of this indication horizontally to intersection with the (vertical) 80° dry-bulb line and the relative humidity reading on the curve is 40%.—Heating and Ventilating Magazine.

EFFICIENCY IN REFRIGERATION

By M. M.

Real efficiency, about which we hear so much nowadays, consists merely in attaining a certain predetermined result by the easiest, quickest and best method. For many years aboard ship the commissary was somewhat of a secondary consideration; in fact, on some vessels the scale dropped even lower, but in any event it was never considered a serious problem. Careful investigation has, however, proved that men do better work, stick by the ship better, and are generally more useful in every respect if they are given plain, nourishing food that has been kept in first-class shape under ideal or, at least, sanitary conditions. In order to maintain such in the food compartments a refrigerating machine or, as it is most generally spoken of, an "ice machine" is essential.

To prove this to your satisfaction, it is only necessary to visit a ship immediately upon her return from an extended trip and look at the interior of the ice box. You will find on the floor racks about one-half ton of ice or less mixed up with various meats of various kinds in different stages of health—some of them comparatively healthy and some of them rather under the weather. You will also probably find a few very much dilapidated fowls that are away off color and very soggy. This is not first-class grub, and the commissary departments are beginning to realize it, so that gradually the various boats of all kinds—freighters, tankers, passenger ships, tugs, etc., are being equipped with ice machines.

When you enter the freezing compartment of a mechanically-cooled box you will find a temperature of two to ten points below freezing point, the air crisp and clear; there are no disagreeable odors, the meat and the poultry are firmly frozen, and thereby immune to deterioration for a long period. This is the theoretical side of the question. Now to come right down to earth and talk about the most important phase of the whole subject, which is the "dollar and cents" side. On one line of steamers, where a very careful record is kept of the "per meal" cost, the actual saving per meal by mechanical refrigeration with a well known system over the old style of ice method of cooling was 3½ cents.

This freighter had thirty men aboard, which at 3½ cents showed a saving of $1.05 per meal, $3.15 per day, or $1,149.75 a year. The plant on their boat cost in the neighborhood of $2,000, so that the outfit was paid for in two years. This is an actual saving when all costs of operation against cost of ice, etc., are taken into consideration. In some cases the saving might be less; in some it might very well be more. The above is cited as an instance to show that in addition to the improved sanitary conditions that are obtained by mechanical refrigeration there is an actual saving in money. Another point in favor of mechanical refrigeration is that whatever you buy in the way of supplies is fully used. Meat with a system installed in a vessel can be carried to the Orient and back in first-class shape, but a ship is lucky that can carry meat half-way across the Red Sea where ice is used as a refrigerant.

GRAND RIVER IMPROVEMENT ASSOCIATION

FOR some years the Grand River Improvement Association has been urging that conservation dams be built to create storage reservoirs on the upper waters of the Grand and of the Speed Rivers.

Noulan Cauchon, the consulting engineer, of Ottawa, who, with W. F. Tye, C.E., consulting engineer of Montreal, has recently urged that the Grand River conservation be carried out not only for flood prevention but to enable the creation of high power and also the irrigation of large areas of the most fertile land in Canada.

Mr. Cauchon proposes a main canal for joint irrigation and power purposes, from a point about three miles below Galt, at the 900-foot level, through a natural pass for some three miles easterly, thence continuing across open level country to the 800-foot level on the escarpment above Dundas. This canal would be about fifteen miles in length. The drop at Dundas from elevation 800 to the Dundas marsh, elevation 245, would be 555 feet within 1¼ miles. The initial power so developed would be from 15,000 horsepower up, according and as fast as more conservation, more reservoirs, be completed.

POWER, COMBUSTION AND SUCH-LIKE

INVENTIVENESS is a trait which finds a peculiarly receptive home in the brain of power house engineers, be they designers or operators. The continuous association with mechanism and the study of the translation of forces from the latent state of nature to the active state of kinetic energy encourages the investigation of problems whose solution frequently necessitates the evolution of new forms of mechanism or the application of known apparatus in new ways.

The lure of perpetual motion has received more or less attention from most men at some time of their lives, and by the time they are of mature age they are, 99 and 9-10ths per cent. of them, reconciled to the fact that it is impossible.

The problem of converting the heat of the sun's rays in useful work is a different matter altogether, the problem there being to do in a short time what nature takes quite a while to do.

It does not take long for a cubic foot of wood to change into CO_2 at the right temperature and under the proper conditions of air supply. It does, however, take quite a while to change that CO_2 back into wood and air through the action of the sun's rays on a plant.

How does the plant do it? Does the "vegetable spirit" play the part of a catalyst by virtue of the life in it, so that the action of the sun's rays on air and air may become effective?

Destroy the "spirit" and the action ceases. All the elements are there as before but all are inactive. The quest of such a source of power is on a par with perpetual motion. The sun is perpetual enough in the ordinary sense of the word, and the two problems may well be classed as unattainable with our present knowledge.

Somewhat akin to these are attempts to use the oxygen in the air as a fuel wherewith to get cheap power. These are due to a misunderstanding of the function of oxygen. All substances which generate heat when uniting with oxygen are combustible. Oxygen is the "combuster." A clear perception of this would save much misspent effort.

THE NEEDS OF CANADA IN REGARD TO INDUSTRIAL RESEARCH

THAT scientific industrial research has proven its worth in cold cash as a business investment was stated by Professor F. C. Fields of Toronto, in a recent public address, although the initial cost of such expenditure is one of the chief obstacles to a more liberal attitude towards research on the part of many manufacturers.

Figures given by Professor Fields regarding such work in America are illuminative:

"In the case of one firm, an investment of $25,000 in two years had yielded assets of $200,000 and an annual profit of $1,000,000. In another case the same investment in 18 months was bringing a profit of $50,000.

"In one instance an investment of $25,000 in four months paid $1,500 per day."

Such instances of course are confined by the nature of circumstances to a limited number of firms, and in the broad national aspect are not of benefit to the population as a whole except via the sales department of the firm making the investment. All that is right and proper, but such a feature differs essentially from British practice which has been considerably accelerated of late.

The "State Department of Scientific and Industrial Research" in Great Britain has a fund of a million pounds sterling at its disposal and among its activities it has been founding co-operative laboratories for manufacturers in similar industries, the department defraying the costs.

The Council of Industrial and Scientific Research in Canada has ample precedent for its existence and while numerically its results may be less than those of similar bodies of other countries, it is a national necessity and as such should be kept closely in touch with by manufacturers throughout the Dominion.

Only by knowing what to look for can the efforts of such an institution be efficiently directed, and while natural resources offer many fields of application, the industrial life of the Dominion will become more consolidated if manufacturers once see the possible benefits to be derived by judicious consultation with the council.

Association and Personal

ANNUAL CONVENTION OF THE CANADIAN ASSOCIATION OF STATIONARY ENGINEERS

The annual convention of the Canadian Association of Stationary Engineers, which will be held at London, beginning June 25, holds promise of being an unusually interesting event.

The convention will be opened by Mayor Summerville on Tuesday, June 25, after which the appointment of the various committees will take place. The afternoon session will be adjourned early in view of the expected trip to Springbank Park, one of London's beauty spots, and well adapted to the holding of the entertainment which will be provided.

Wednesday morning will be given over to a business session, and after lunch an excursion has been arranged for, through the courtesy of the C.A.S.E. Exhibitors' Association, to Port Stanley. Refreshments, sports and games will be held at Port Stanley, and on the return to London in the evening an entertainment will be provided also by the Exhibitors' Association. The Thursday sessions will be fully taken up with election of officers and other business.

Special provision has been made for the entertainment of the ladies, and it is expected that several visits to local plants manufacturing household goods and provisions will be made.

G. W. Ketter has joined the staff of the Electric Furnace Construction Co., Philadelphia, having resigned his position with the British Forgings Co., Ltd., Toronto, Ont.

Herbert A. Jackson was recently elected president of the Chicago Pneumatic Tool Co., Chicago, to succeed W. O. Duntley, resigned. He was born in Bethlehem, Conn., July 7, 1881.

R. D. Smith has recently been appointed to the position of Steam Superintendent for the Wayagamack Pulp Mills at Three Rivers, Que. Previous to his leaving for Three Rivers, Mr. Smith was chief engineer at the Windsor Station, Montreal, Que.

John Hale, executive secretary of the Canadian Association of Stationary Engineers, Hamilton, Ont., has been in hospital for the past two weeks undergoing an operation. His early and complete recovery is hoped for by his wide circle of friends and acquaintances.

LIEUT. PEILER

Who has been reported prisoner, unwounded, in Germany.

Pte. Harold F. Fogarty, formerly on the editorial staff of POWER HOUSE, is in a hospital in France suffering from a gunshot wound in the chest. Pte. Fogarty went overseas with the 198th Battalion early in 1917, but was later transferred to another unit. His home is in Port Hope, Ont.

H. L. Peiler, general manager of the Mason Regulator and Engineering Co., Ltd., Montreal, has received word that his son, Second Lieutenant Maurice F. Peiler, R.F.C., is a prisoner, unwounded, in Germany. He had previously been reported missing on April 6. Lieut. Peiler was born in Montreal twenty-one years ago and was educated at the Montreal High School, Berthier Grammar School and Montreal Technical School. For two years he was with the St. Catherine Street branch of fthe Molsons Bank, and later accountant with his father's business. He went to Toronto July 6 last and was given his wing as a qualified scout pilot eleven weeks later, was in training in England at the end of October, requalified on November 23, and on the 30th of that month was in France on active service. On February 26 last he downed his first Hun 'plane and bagged two more enemy machines on the 13th of last month.

On April 25 the death in action of Captain Michael Chapman was announced. He was well known to the machinery and electrical trade in Canada, having been for some years a member of the firm of Chapman & Walker, Ltd., electrical engineers and dealers in machine tools and supplies. This business continued from 1909 until the outbreak of the war in 1914, when Mr. Chapman enlisted, taking his officer's course and getting a commission first as lieutenant, being advanced to the rank of captain afterwards. Deceased came to Canada from England, where he was formerly with Crompton & Co., at Chelmsford, Essex. On coming to this country he was for a time with the Canada Foundry Co., going into business with Mr. Walker at a later date. He was married, and is survived by a widow and two children, the family being in England at the present time.

The late Captain Chapman had been previously wounded in the war, and won the Military Cross for bravery in action during some of the heavy fighting in February. He was with the Grenadier Guards, a regiment to which he was attached shortly after entering the service. Not long ago he wrote to a close friend, part of his letter being as follows: "If I am killed I want you not to fret or mourn for me. It is a fine death for a great cause." Of him the Colonel of the regiment wrote: "The example he set everyone was glorious. He died more than upholding the honor of our great regiment."

OPERATOR ORGANIZATIONS

British Columbia Association of Stationary Engineers, Vancouver.—Subordinate Lodges at Vancouver, Victoria, New Westminster, Cumberland, Merritt, and Fernie.

North-West Association of Stationary Engineers, Edmonton, Alta.

Manitoba Association of Stationary Engineers, Winnipeg.

Canadian Association of Stationary Engineers, Hamilton, Ont.—Subordinate Lodges at Montreal, Toronto, Hamilton, Ottawa, Brantford, Guelph, Kitchener, Chatham, Ont.; St. John, N.B.; Owen Sound, London, Stratford, Belleville, Kingston, Sudbury, St. Thomas, North Bay, Port Arthur, Sarnia, and Windsor, Ont. The executive officers of the C.A.S.E. Grand Lodge are as follows:—

Past President—W. G. Forbes, Montreal, Que.
President—R. F. Gofton, Kitchener, Ont.

The Operators' Point of View

OXYGEN AND ITS COMBUSTION

IN criticising your article in February issue re oxygen for power engines, it was not my intention to open any useless controversy, but merely to question the accuracy of your correspondents information.

However, since Union Engineer has seen fit to question my knowledge of the subject, and incidentally my standing as an engineer, it devolves upon me to take up the cudgels in my own behalf, as unfortunately upon my reputation depends my bread and butter. So I must ask for more of your valuable space.

I might state for Union Engineer's benefit, that I am personally known to both the editors of this magazine, and also to the business agent of Local 152. Union Engineer asks, "Since when have we been dependent on combustibles for use in engines as a motive force?"

If a dictionary be consulted it will be found that combustible is a term which is applied to anything that will burn. So that the question is, since when have we been dependent on things that will burn for use in engines as a motive force?

As an answer to that question, I will ask another. Since when, (excepting wind and water power), have we not been dependent on things that will burn for motive power? True, steam and compressed air are not combustible, but the coal that was used to raise the steam must have been. So that for steam engines we certainly are dependent on combustibles for motive force.

But anyway, neither steam or compressed air are motive forces, they are simply the vehicles used to convey the power contained in the coal and liberated by its combustion to the engines in question.

Union Engineer certainly has some peculiar ideas regarding combustibles, when he says that gasoline is not combustible until mixed with air. Evidently he is confused with the terms combustion and explosion, or rather combustible and explosive. (By the way I wonder if Union Engineer, ever placed a lighted match in contact with gasoline and noted the result).

The same dictionary mentioned before would say that explosion was combustion so rapid as to be instantaneous. But whilst an explosion is combustion, combustion is not necessarily an explosion. An explosion only takes place when all the elements necessary for combustion are intimately mixed. So that a mixture of gas and air, gasoline vapor and air, oil, vapor and air, coal dust and air, and many others, are explosive mixtures.

Union Engineer, says that hydrogen and oxygen can be reduced to liquids, and expanded like steam, to drive engines in the same way as steam. Very true, but these would not be motive forces, but as in the case of steam and compressed air, simply vehicles; but anyway, where would U. E. get the power from to compress these gases, and what percentage of the power used to compress them would be available for use in the said engines?

When Union Engineer begins to study chemistry he will find that oxygen is a colorless, odorless gas which is not combustible, but which very strongly supports combustion. Further it forms one-fifth of the atmosphere by volume, eight-ninths of water by weight, and about 50 per cent. of the earth's crust by weight.

In the original article which started this controversy, oxygen was mentioned as taking the place of gas, oil, or gasoline in an "internal combustion" engine. Union Engineer seems to have lost sight of those two words, for in my opinion they presuppose the existence and use of some combustible.

In the ordinary internal combustion engine, oil, gasoline, gas, or alcohol, are combustibles most frequently used. However there can be no combustion without air, or rather oxygen, and as air is the cheapest source of oxygen, a mixture of the combustible (in vapor form) and air is used. As there could be no combustion without oxygen, neither could there be any combustion without the combustible. If there could be such a thing happen, we should be able to raise steam without burning coal.

Union Engineer presumes that the inventor intends to use oxygen from the air in the same way as gasoline is used, combining hydrogen with oxygen, etc, Very good, but there is no mention of hydrogen in the original article. Anyway, why use hydrogen, when oil and gasoline are already to hand and cheaper to obtain?

There would be no difficulty in regulating a mixture of hydrogen and oxygen gases in an engine cylinder, nor is there any difficulty in the way of using acetylene:—if—they were cheap enough. If the present engine designs are not suitable for these gases, it is quite possible to obtain some which would be.

In regard to the activity of nitrogen possibly the following combustion equations might enlighten U. E. a little.

Combustion of Carbon—

$$\underset{\text{Carbon}}{C} + \underset{\text{Air}}{(4\,N_2 + O_2)} = \underset{\text{Carbon Dioxide}}{CO_2} + \underset{\text{Free Nitrogen}}{4\,N_2}$$

Acetylene—

$$\underset{\text{Acetylene}}{2\,C_2H_2} + \underset{\text{Air}}{5(4\,N_2 + O_2)} = \underset{\text{Carbon Dioxide}}{4CO_2} + \underset{\text{Water}}{2H_2O} + \underset{\text{Nitrogen}}{20N_2}$$

Black Powder—

$$\underset{\text{Potassium Nitrate}}{2\,KNO_3} + \underset{\text{Carbon}}{3C} + \underset{\text{Sulphur}}{S} = \underset{\text{Potassium Sulphide}}{K_2S} + \underset{\text{Carbon Dioxide}}{3\,CO_2} + \underset{\text{Nitrogen}}{N_2}$$

Nitroglycerin—

$$\underset{\text{Nitroglycerin}}{2C_3H_5(ONO_2)_3} = \underset{\text{Carbon Dioxide}}{6\,CO_2} + \underset{\text{Water}}{5\,H_2O} + \underset{\text{Nitrogen}}{6N} + \underset{\text{Oxygen}}{O.}$$

As I understand the term "active element," it means that the element readily combines with other elements to form compounds. With this in mind, the equations given do not show nitrogen to be a very active element, as in every case free nitrogen was evolved. I would like to cay that as far as I am concerned the subject is closed, as it is not my intention to write again on this subject.

Union Engineer's remarks, whilst of interest have failed to remove my original doubts, although they have removed some others. But why does not Union Engineer come from out of his ambush, and use his own name? It is possible that he may be convinced that there is no push in oxygen used as a base like gasoline, for if he really studies the question he will find that is impossible.

In conclusion I would quote for Union Engineer's consideration that old saying attributed to the Duke of Wellington, "Be sure you are right; then go ahead."

S. BALMFIRTH.

Correspondent's Discussion

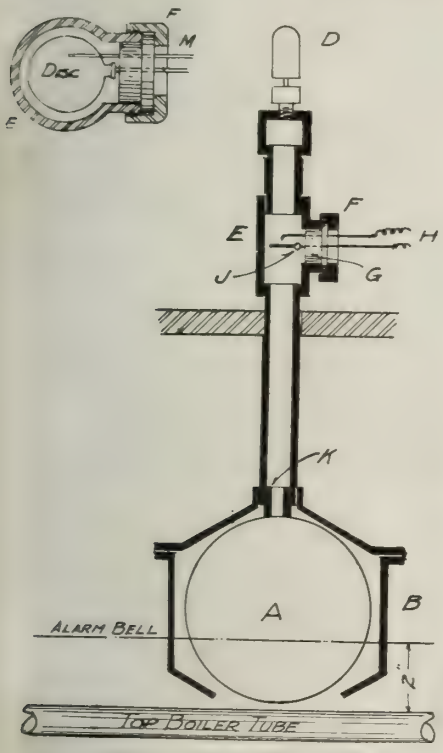
Attention of correspondents is drawn to the customary condition whereby the real name and address of contributors (not necessarily for publication) must accompany all articles. In view of this we are compelled to discontinue the above discussion, and also hold back several other articles.

IS EXHAUST STEAM HOTTER THAN LIVE STEAM?

When discussing power house problems with an engineer recently, the writer was asked the above question, and promptly replied "neither," presuming, of course that equal pressures existed. The question came up through the assertion that it was easier to keep a heating system in order with exhaust steam than by using live steam direct from the boilers; it took less steam, judged by the coal consumption of the boiler.

If any readers of POWER HOUSE have actual experience of such conditions it would afford interesting matter for discussion. Can you oblige?

Toronto J. W. MAXWELL



A NEW LOW-WATER ALARM

A NEW LOW-WATER ALARM

By John Port

The low-water alarm for steam boilers shown in the sketch is a new idea as to design. In Fig. 1 a seamless, heavy, copper or brass float ball is shown at A. It is held in place by an iron casing B; an extra heavy piece of iron pipe, ¾ inch, is screwed into the float casing and through the boiler shell. A brass seat piece is screwed into the pipe end at K; a sectional view of a tee is shown at E, and a plan view of the same tee in the upper view.

One end of the tee (the center) is filled with a strong insulating material at G; through this material passes two iron rods ,a brass disc is hinged to one of the rods at J (the top rod is shown to one side in Fig. 2 for clearness). To the outside ends of these rods the terminals of a bell-ringing outfit are connected, H; the bell can be in any place desired, such as the manager's office in some other building. Above the tee is a nipple and a small whistle, D. When the water in the boiler lowers to a dangerous level the float drops and steam passes up through the hole at K; it forces the disc against the other or top rod and rings the bell in the office, also the steam whistle blows. As soon as the water reaches a safe level the float raises and closes the vent at K, and the disc drops back. The principle of the ball and vent is the same as that used in a well-known steam trap, only it works in exactly the opposite way. The ball opens when the water is high in the steam traps. The ball closes the opening when the water is high in the alarm.

THE ART OF FIRING

By N. G. Near

W. H. A. says in the April number of POWER HOUSE, page 110:

"To be sure there is no great art in wheeling coal or shoveling it into the furnace. Where the art comes in is in putting it into the right place at the right time."

While it is true that in hand firing it is necessary to put the coal in the right place at the right time, the writer is inclined to question the completeness of this declaration. There are so many other things to be considered that in my mind these two little points sink into almost insignificance.

How about the air? Isn't it a fact that the regulation of air is about the most important point of all? Complete combustion means much more than that all of the coal be consumed. It is easy enough to burn up all the coal and have only ash remaining. What we want is efficient combustion, and the only way in which efficient combustion can be attained is by properly proportioning the air, by keeping the fire clean, by eliminating air-infiltration, by maintaining the correct thickness of fire, and that is perhaps all so far as combustion itself is concerned.

Then we have the soot question. No matter how careful the fireman is he is going to produce soot in greater or lesser degree and he must keep it off of the tubes as completely as possible. That is quite a job in itself. The old hand lance will do the work better than no cleaning method at all, but there is a more modern method these days—the installation of a permanent soot cleaner. And that isn't all either; the soot cleaner must be used. The mere installation won't help a bit unless the elements are swung around with steam turned on about three or four times per day, depending upon the kind of coal used, the load carried by the boilers, etc. The jets sweep down between the tubes from the right side and from the left, and in cyclonic fashion clean off the offending soot and ash deposits. A great deal of the matter adhering to or lying on the tubes is not soot at all, you know, but is some form of ash. It is really surprising the number of colors and kinds of ash that have been found in boiler tubes. The soot cleaner problem does not strictly come under the heading of "combustion," yet it is a part of the fireman's job to keep the tubes clean, and should be added to the "art" W. H. A. speaks of in the April number.

More closely associated with combustion is the CO_2 recorder. Combustion, you know, is a chemical process, that is why so few of us understand combustion. It is quite possible that nobody living understands combustion. We can talk and write about it glibly enough, the atomic and molecular theories sound perfectly plausible. It is learned that the elements combine in a certain way every time, that laws can be made which are followed to the dot by the combustion process, but beyond that we are helpless. The writing I am doing here is not adding one whit to our knowledge, either, but these thoughts are my own and I am always willing to trade thoughts and ideas for someone else's thoughts and ideas. So, we will simply leave it to the chemist to do the best he can in the matter of making a CO_2 machine for us that will automatically and continuously record the CO_2, for there is nothing more important in combustion than to maintain the proper percentage of CO_2.

Some engineers have the idea that the percentage of CO_2 should always be as high as possible, but not so. By making it too high there is danger of getting too little air, so we are told. It is better to run on a little less than the theoretical maximum by using a surplus of air than to use the exact theoretical mixture and consequent imperfect combustion. It takes time for the gases to mix in the burning process, and ordinarily, if a surplus of air is not admitted, the gases strike the comparatively cool tubes, the temperature of the gases drops below the temperature of combustion, good carbon is deposited on the tubes, good CO escapes up the chimney, and the owner is virtually throwing money away up the flue by attempting perfect combustion. A surplus of air hastens the combustion process, and even though there is a loss involved in wastefully heating the surplus air it is better to suffer that loss than to permit the greater one where CO escapes unburned.

The most modern method of handling the CO_2 question is to have a recorder in the chief's office which permits him to keep a constant eye on combustion efficiency, and at the same time keep a CO_2 indicator on the boiler front in full view of the fireman. It is the duty of the fireman to keep the CO_2 at the most economical point.

Lastly, the fireman who must use his good old muscle in feeding the furnace is handicapped in constantly maintaining the right percentage of CO_2. If he could throw the coal into the furnace without opening the fire doors it would be much nicer, but that method hasn't been invented yet, so far as the writer knows. When the door is opened the CO_2 drops. With an automatic continuous stoker it is a simpler matter to maintain constant CO_2.

Progress in New Equipment

A PLASTIC REFRACTORY FOR BOILER BAFFLES

THE principal loss of heat from a boiler furnace is in the flue gases, and is measured by the product of their weight multiplied by their excess of temperature over atmospheric temperature. High temperature of gases may be due to coming into contact with too little heating surface, to coatings of soot or scale upon the heating surface, which prevent the absorption of heat from the gases, but most commonly to defects in the baffling. Baffles may be improperly located, producing dead spaces where the gases do not circulate in the tube banks of water tube boilers, or the baffling may not provide for a sufficiently high velocity and long path of the gases of combustion.

Defective baffling is the most common cause of high chimney temperatures. The baffles may have fallen down or bricks or blocks may have slipped out from between the boiler tubes, allowing the short-circuiting of a large amount of gas.

The strongest reason for the installation of pyrometers to measure flue gas temperatures is that they serve to notify the operating force at once regarding baffle failures. Where abnormally high temperatures are found a broken-down baffle is always to be expected.

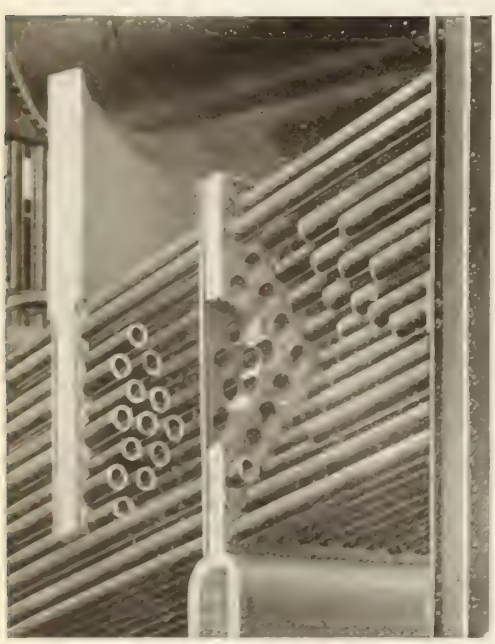


FIG. 1. BETSON PLASTIC FIRE BRICK BAFFLE IN A B & W VERTICAL HEADER BOILER.

Baffles for water-tube boilers have in the past consisted of tile, bricks or blocks of refractory material fitted in between the tubes. In cross-baffled boilers these tiles are introduced between the tubes by springing the latter, and naturally do not form very tight joints with one another or with the tubes, especially after the latter have become warped or sprung, as they invariably do, in service. It is also difficult to insure that blocks will remain where they are placed and will not slip or fall, leaving large openings. Due to the manner in which baffles are inserted in boilers, it is almost impossible to cement them together, besides which the difference in expansion and contraction of the boiler and baffling would break the joints apart. Brick and blocks also warp and twist, and are frequently split by the pinching effect of the tubes.

The accompanying illustrations show how jointless and, therefore, gas-tight baffles can be made by the use of a refractory known under the trade name of plastic fire brick, and manufactured by the Betson Plastic Fire Brick Co., of Rome, N.Y. This material was originally introduced for lining boiler furnaces, and is compounded of refractory materials so prepared as practically to eliminate expansion and contraction with changes in temperature.

The material is shipped in barrels in a moist, plastic condition, ready for use. In forming a cross baffle for a water-tube boiler of the B. & W. type the ordinary cast iron baffle plate is used as one side of the mould, while the other is made by thrusting slats in through the diagonals between the tubes, as shown in Fig. 2. The plastic material is then poked down through the diagonals to fill the space between the cast iron baffle plate and these slats. It is sufficiently plastic, so that it can be forced out sidewise around the tubes, fitting the latter sngly.

When this work has been completed the boiler is fired up slowly, the criss-cross of slats burns out, and the plastic material is dried and vitrified in place. This operation occupies only a few hours, after which the full load may be put upon the boiler. Inasmuch as the boiler comes up to full steam pressure before the material is thoroughly set, the expansion of the metal pushes away the soft material to the position which it should occupy when the boiler is hot, and while the boiler will draw away from the material in cooling off again, the baffles will always fit tightly when the boiler is under steam.

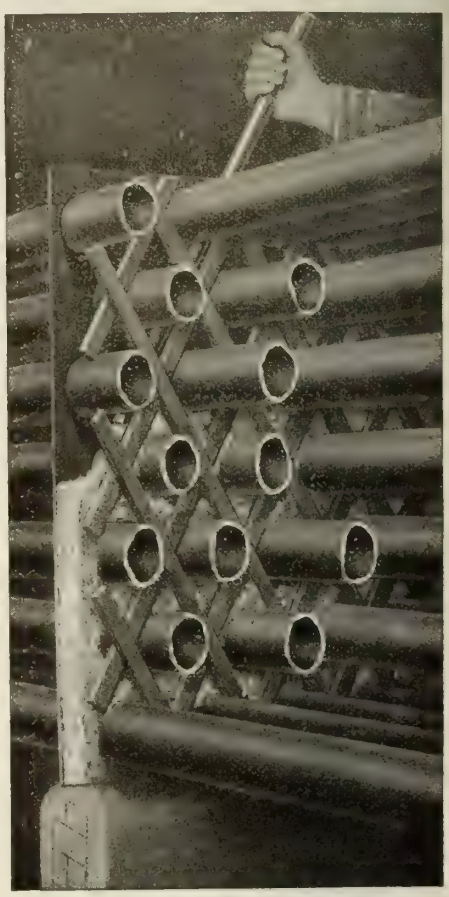

FIG. 2. METHOD OF PLACING AND COMPACTING THE MATERIAL, WHICH IS RETAINED IN PLACE BY A CRISS-CROSS OF SLATS UNTIL SET BY THE FIRE

In forming a longitudinal baffle blocks of wood are placed in between the tubes above and below the space which it is desired that the baffle shall occupy, thus confining the plastic material, which is shoved in from the side in the case of baffles in the middle of the tube bank, or from underneath or overhead in the case of the baffles at the bottom or top of the tube bank.

Referring to the illustration, Fig. 4, the slats (S) are placed in position between the tubes (T), as shown (second row), and are held in place by balls of the material jammed under them. This material is then pushed into the space (B) and rammed with the end of a piece of 2 by 4. Starting work on each side, the operator works towards the middle. As fast as a section is done the lower slat (S) is placed as shown until all slats are in place on the lower row. Fire

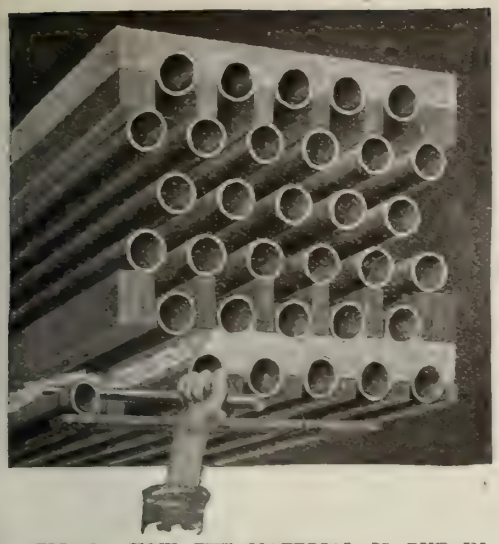

FIG. 3. HOW THE MATERIAL IS PUT IN PLACE TO FORM HORIZONTAL OR LENGTHWISE BAFFLES IN WATER TUBE BOILERS

slowly at first, as described under vertical baffles.

Where this material is used, there is no restriction upon the shape or size of the baffle, and the latter can, therefore, be arranged in any form desired. In cross-baffled boilers, for example, it is becoming the practice to slope or incline the baffles, so that the gas passage will contract progressively from the point where the gases enter the tube to the point where they leave, in order to maintain a uniform gas velocity, in spite of the shrinkage of gas volume with cooling. This is easily accomplished with the plastic material, whereas with the solid bricks or blocks a special block is required, which can be inserted and maintained in place only with difficulty, if at all.

This material also finds use as a substitute for special forms of bricks or blocks, as for example, where the front headers of horizontal water-tube boilers rest upon the front arch. Its use for lining furnace and combustion chambers, including front arch, side walls, bridge wall, rear arch, etc., has been described previously. The exacting tests to which it has been put in direct contact with the fuel bed and with the gases of combustion before they have been cooled by the boiler surfaces proves its ability to withstand high temperature gases and stresses such as are encountered in furnace construction for long periods without crumbling or otherwise deteriorating.

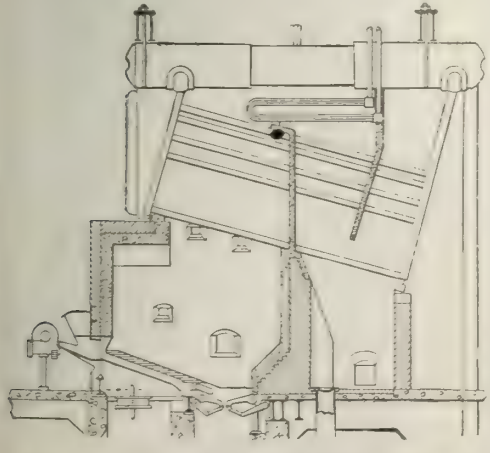

FIG. 4. THE PLASTIC MATERIAL CAN BE USED FOR SLOPING BAFFLES AND TAPERING GAS PASSAGES

POCKET CO_2 INDICATOR

A RELIABLE indication of the character of combustion in any furnace is the percentage of CO_2 in the gases of combustion. The higher the latter can be raised the greater will be the economy in fuel. For the complete combustion of coal, gas, oil, or any other fuel, a certain definite quantity of air is necessary. Too little air will result in a portion of the heat value of the fuel going up the stack unconsumed, and in being entirely wasted. The other extreme, however, is usually experienced in the average furnace. Too much air is supplied, which results in a cooling down of the furnace gases; at the same time the temperature of the excess air has to be raised from room temperature to that of the stack, usually 500° Fahr. or more, which is an absolute waste.

The curves in the chart, Fig. 1, show that for coal-fired furnaces, about 40 per cent. of excess air is necessary to obtain the most efficient combustion. This is indicated by the highest CO_2 contents obtained by this amount of air as shown by the two curves. A greater percentage of excess air reduces the CO_2 contents and therefore increases the fuel loss. Thus, for 300 per cent. excess air the CO_2 drops to 5 per cent., while the corresponding fuel loss becomes 21 per cent.

A portable CO_2 indicator has recently been placed on the market by the Bacharach Industrial Instrument Co., Pittsburg, Pa., and as will be seen from the accompanying illustrations it is much more convenient and simple than the bulky Orsat apparatus usually employed.

A test takes about 2½ minutes, and it is possible to go from boiler to boiler and make about 20 tests an hour.

With ordinary care an analysis can be made with a maximum error of plus or minus 0.2 per cent. The reagent is a solution of potassium hydroxide in water, and several hundred analyses can be made with one charge of caustic.

In using the indicator the two cocks A and B are first put in place and the glass jar F at the lower end removed and filled with the analyzing solution, after which it is screwed on again. The

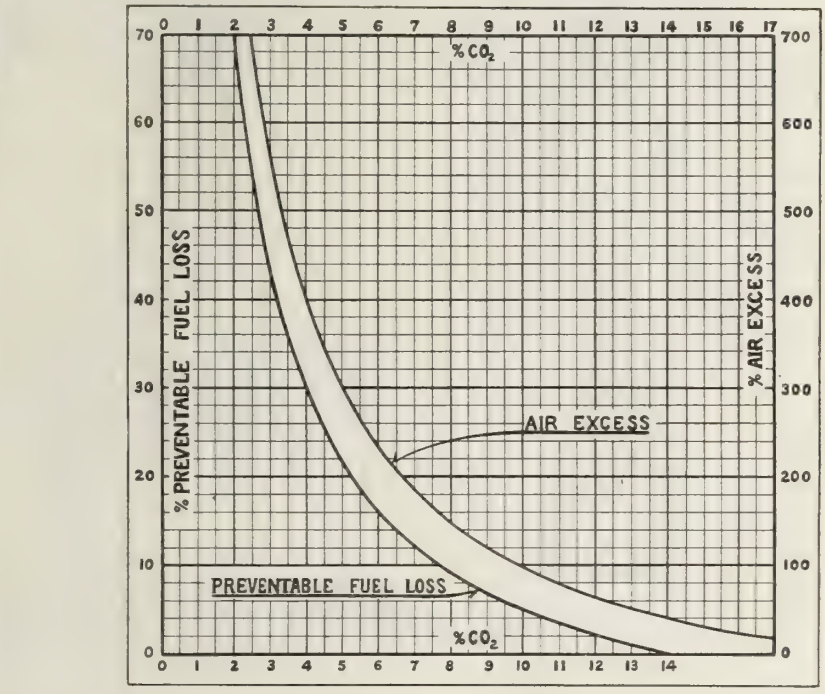

FIG. 1—CURVE SHOWING RELATION BETWEEN EXCESS AIR AND PREVENTABLE FUEL LOSS.

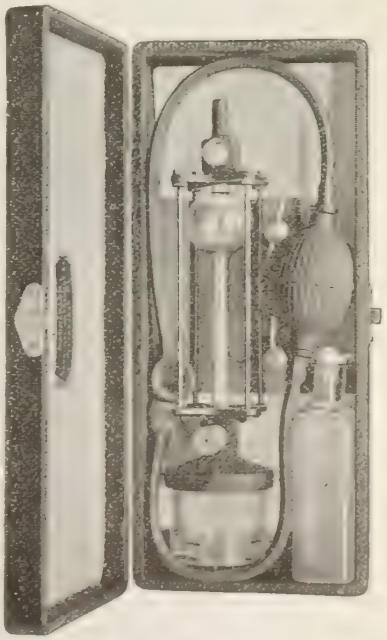

FIG. 2—CO INDICATOR IN CASE.

pump is attached to the open upper valve and the cock A of the lower valve turned so that the gas measuring tube H is open to the atmosphere through the hole C. The open end of the pump is then connected to the gas line from which the sample is to be taken, and the gas pumped in, a fair sample being taken, about 30 strokes of the pump be-

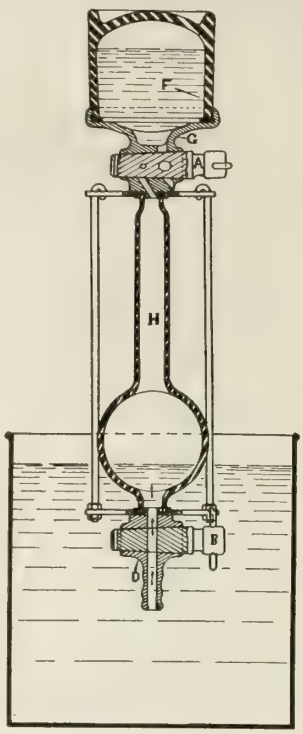

FIG. 5—ADMISSION OF WATER FOR MEASURING PURPOSES.

ing sufficient. The upper cock B is then closed.

The lower cock A is then turned 180° to permit the gas and KOH to come into contact for chemical action, the process being helped by holding the apparatus in an inclined position as shown in Fig. 4. When the solution has been drained

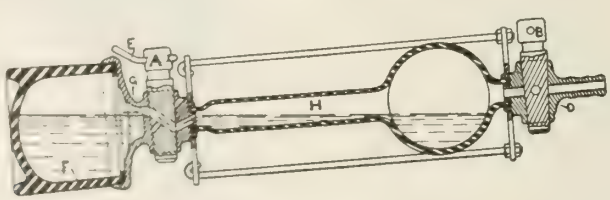

FIG. 4—APPARATUS HELD IN INCLINED POSITION.

back to the glass jar F the lower cock A is closed and the indicator held upside down and immersed in water, Fig. 5. The submerged cock B is opened and the ingoing water which takes the place of the absorbed CO_2 is levelled with that outside. The cock B is then closed, the indicator brought to its base, and the per cent CO_2 read off on the tube at water level. The water is emptied by opening the cock B and turning the apparatus upside down.

ELECTRIC MONO-RAIL HOISTS FOR HANDLING ASHES

THE three accompanying engravings show the electric mono-rail hoist as manufactured by the Link-Belt Co. of Chicago, Ill., in actual service as an ash conveyor in Fig. 1 and 2 and a coal conveyor for filling the stoker hoppers in Fig 3.

It is designed primarily to afford an ash handling system for old boiler houses whose construction does not provide the modern labor saving devices, nor room for same and which would not warrant the expenditure nor the maintenance involved in the installation of a very elaborate equipment.

In such instances the mono-rail hoist will appeal on the grounds of low first cost and maintenance, the greater ash handling capacity and ease of handling, the small space requirements and simplicity of installation, as well as the ease and efficiency of operation.

The machine consists of hoist carriage with trailer cage which runs on the lower flange of an I beam track. The operator controls the raising and lowering of the bucket as well as the travel of the hoist from the cage. The capacity of

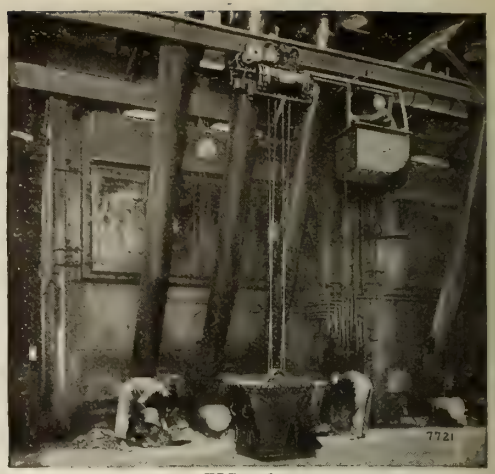

FIG. 1.

the bucket is 1¼ cubic yds. and the lifting capacity of the hoist is 2 tons. All the gears operate in oil and are entirely enclosed in housing as is necessary considering the material handled.

In many instances where it is advisable to instal stokers to increase the ca-

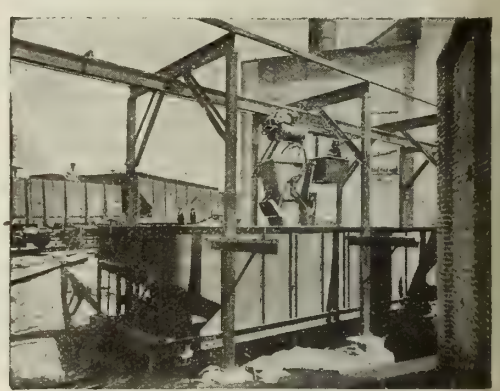

FIG. 2.

pacity of the plant, lack of space would militate against installation of overhead bunkers. It may then be practical to use the mono-rail hoist system to handle the coal as well as ashes. Cut No. 3 shows a tipping bucket about to discharge coal into a stoker hopper. A bucket with a small chute and under chute could be used to advantage for this work.

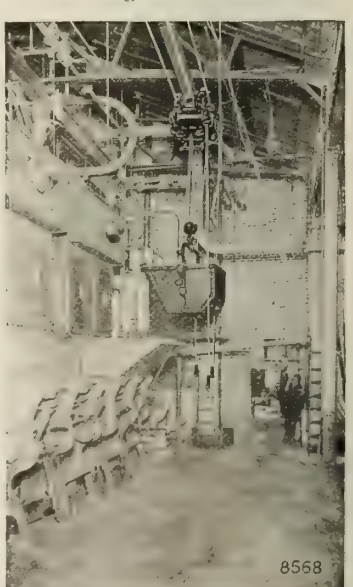

FIG. 3.

Operators' Instruction Course

EDUCATION PAPER VII

WHAT is the horsepower of a boiler 66 in. diameter, 16 ft. long, with 78 only 3½ in. tubes?

It is customary to allow 12 sq. ft. of heating surface to a boiler horsepower when dealing with horizontal return tubular boilers. The heating surface is taken to be the full area of the boiler tubes and one half the area of the shell. A 3½ in. tube has a heating surface of .9163 sq. ft. for each foot in length, and 78 tubes 16 ft. long will have an area of 78 x 16 x .9163=1,143.6 sq. ft. The heating surface (effective) of a 66 in. shell is 8.64 sq. ft. per ft. in length and so therefore a shell 16 ft. long has a heating surface of 8.64×16=138.24 sq. ft.

The total heating surface is 138.24+1,143.6=1,281.84 sq. ft.

The horsepower is 1,281.84÷12=107 nearly.

* * *

If the pressure shown on a gauge is 95 lbs. per sq. in. what is the height of the water?

The height of a column of water corresponding to a given gauge pressure may be found by multiplying the observed gauge pressure by 2.3. Therefore 95×2.3=218.5 ft.

* * *

What is the pressure at the column of water 250 ft. high?

The pressure in pounds per square inch corresponding to a given height in feet may be found by multiplying the given height in feet by .43. Therefore 250×.43=107.5 lbs. per sq. in.

* * *

What is the grate bar area of a furnace 5 ft. 5 in. wide by 6 ft. long?

The grate area is 5 ft. 5 ins.×6=32½ sq. ft.

* * *

How many gallons of water will be pumped in one hour by a duplex steam pump 6 in. in diameter by 10 in. stroke, running at 60 strokes per minute, allowing 10 per cent. slippage?

The area of a circle 6 in. diameter expressed in square feet is .1963 and the volume of water pumped in one stroke of the pump is .1963×10÷12=.1635 cu. ft. The volume pumped in one hour, taking into consideration the 10 per cent. slippage will be .1635 x 60 x 60×90/100 =529.74 cu. ft., or 529.74×6¼=3,311.4 imperial gallons.

* * *

What is the horsepower of an engine 25 in. by 50 in., running 65 revs. per min., with a m.e.p. of 51.5 lbs.?

The horsepower of an engine is given by the formula:

$$\frac{\text{PLAN}}{33{,}000}$$

Where—

P=the mean effective pressure in pounds per square inch
A=Area of piston in square inches
N=Number of strokes per minute.
L=Length of stroke in feet.

The area of a 25 in. cylinder is 490.874 sq. ins., the length of stroke is 4.125 ft., and the number of strokes is 130 per min. Substituting in the formula we obtain, 51.5×490.874×4.125×130÷33,000=410.8 indicated horsepower.

BITUMINOUS COAL OUTPUT SHOWING STEADY INCREASE

THE United States Geological Survey issues the following report on the production of bituminous coal and the causes of loss of working time for the week ending May 4, 1918:

The week ended April 27 recorded not only the highest rate of production of bituminous coal during the past 12 months but the third successive week of rising production.

Production of bituminous coal (including lignite and coal made into coke) is estimated at 11,668,000 net tons, an increase of 5.7 per cent. over the preceding week. The average production per working day is estimated at 1,946,000 net tons compared with 1,840,000 net tons last week, and 1,680,000 net tons during April, 1917.

Production for the month of April, 1918, is estimated at 46,478,000 net tons, an increase of 4,400,000 net tons or 10 per cent over April of last year. Production for the four months ended April, 1918, is estimated at 181,992,000 net tons, an increase of over 5,000,000 net tons or 3 per cent compared with the same four months of 1917.

The production of beehive coke during the week ended April 27 is estimated at 652,000 net tons, compared with 614,000 the week previous. The average daily production is estimated at 109,000 net tons, an increase of 7 per cent over last week. Anthracite shipments slightly increased during the week of April 27, nine roads reporting 39,522 carloads compared with 39,130 during the preceding week.

POWER DEVELOPMENT NEAR MONTREAL

IN view of the present interest in the power development in Montreal and Quebec province and the apparent need of further development in the near future, the fact that Montreal Power can develop 300,000 horse power against the 240,000 which it will have by midsummer will be of interest.

The present capacity of Cedar Rapids is 100,000 horse power, though the water power development is 180,000 horse power; units to develop 20,000 horse power are now being installed, and will be completed by the end of July, when the power from the plant will be 120,000 horse power units, for the remaining 60,000 horse power will be installed as required.

Lachine and Soulanges plants develop from 12,000 to 15,000 horse power. The contract with Shawinigan would give the Power 65,000 to 75,000 horse power.

The situation is that in a couple of months the company will have a nominal capacity of 240,000 horse power hydro-electric for distribution, and may increase this to 300,000 horse power hydro-electric simply by adding necessary units. In addition, its auxiliary steam plants have a capacity of 30,000 horse power available at any time.

This may be divided approximately, as follows:

	H. P.
Power Co's. Chambly plant	20,000
Power Co.'s Lachine plant (12,000 to 15,000)	12,000
Power Co's. Soulanges plant (12,000 to 15,000)	13,000
Power Co's. Cedars Rapids by July 31	120,000
Shaw W. & P. on contract	75,000
Hydro-electric power available by August	240,000
Cedars Rapids additional unit capacity	60,000
Hydro-Electric, totals	300,000
Capacity Co's. steam auxiliaries	30,000

FOR some time a fairly regular aerial mail service has been established between Italy and Sicily, in lieu of the former somewhat unsatisfactory combination of railroad and ferry. The trip by aeroplane occupies some three hours, and by leaving Naples in the morning the aeroplane can return from Palermo in the early afternoon.

The "BULLDOG" Cleaner for straight tubes—3½ and 4 in. sizes

Engineer Duke was so sure of his "Bulldog's" ability that—

but read this fact story yourself

Frank K. Duke is a prominent Philadelphia engineer. At a plant near his own they decided to buy a boiler tube cleaner that was not a "Bulldog."

Mr. Duke had a "Bulldog" and to him it was the **only** tube cleaner worth having.

"Hold on!" he said to his neighbor. "Try another make of cleaner if you want to but try my 'Bulldog' in comparison with it—and don't buy before you do try."

He actually sent his "Bulldog" Cleaner over to them, loaned it to them for the trial—

And as usual, the "Bulldog" Cleaner proved its superiority. It emerged from that trial indisputably the winner.

We don't know of any more convincing experience than this in proving not only that the "Bulldog" is as good a scale remover as you'll find anywhere, but also that no one appreciates that fact so well as the engineer who uses a "Bulldog." When are you going to purchase yours?

If you want some real definite information on scale fighting, send for our Catalogue "H." It describes the "Bulldog," also all types of Liberty Cleaners—a Cleaner for every purpose and every condition.

Liberty Manufacturing Company

6904 Susquehanna Street

Pittsburgh Pennsylvania

The "BULLDOG" Cleaner for bent tubes—3 and 3¼ in. sizes.

SARCO Is Set for YOUR Work at Any Point—Range 30 degrees to 300 degrees Fahrenheit

Change SARCO at Will to Suit Variations in Conditions—Range 20 degrees —10 degrees Up or Down

SARCO Temperature Regulator HOLDS Temperature Set

Our engineers study your own particular Temperature Regulator problems. Then we furnish SARCO Temperature Regulator, set to suit your work; 30 to 300 degrees F. for regular SARCOS. Extra ranges made at slight extra expense. First step of SARCO Service.

But we also give you a range of 10 degrees above or below the point at which SARCO is set to change the operating point. Simply turn the regulating screw. Invaluable where a different lot of materials, or other causes, require variations in process. Second step in SARCO Service.

Once set, SARCO eternally holds the temperature point. Works instantly to correct variations. Saves heating or cooling mediums. Saves spoilage. Eliminates errors and the human equation. Lasting, unaffected by anything — except temperature. Third step in SARCO Service.

Then we furnish SARCO valves adapted to the circulating medium you use — water or other liquids; steam or gas.

Also Thermostats that resist corrosion in any place they are designed to be inserted. Durability, permanence. Fourth step in SARCO Service.

Why SARCO is so simple, durable and effective is owing to the scientific principles on which it is constructed. Fully explained in a booklet, Give SARCO a free trial.

TRADE GOSSIP

Renfrew, Ont.—The Roberts Filter Mfg. Co., Philadelphia, have the contract for filters costing $6,000, for the City Council.

Galt, Ont.—The Grand River Railway, which has been operating by Hydro, has been ordered by Sir Henry Drayton to start its steam plant.

Springfield, Ont.—The Canadian Ice Machine Co., Toronto, have the contract for refrigerating plant for the Springfield Milk Co., who are receiving prices for the supply of piping for water, steam and air.

To Develop Power.—North Vancouver contemplates the purchase of power site of the Naire Falls Power Co. The figure will be approximately $75,000. The idea is to secure a supply for the domestic lighting and heating of Greater Vancouver.

Dodd Heating Systems Ltd., has been incorporated at Ottawa with a capital of $100,000 to manufacture heating, lighting and power appliances and apparatus, etc. at Toronto. The incorporators are John O'Neil, H. S. Dodd and J. Sheedy, all of Toronto.

Canadian Graton & Knight, Ltd. has been incorporated at Ottawa by R. H. Jackson, F. P. Brais and J. Bruneau, all of Montreal, to manufacture leather belting and leather sundries of all kinds. The capital stock is $100,000 and the chief place of business is Montreal.

Build New Plant.—The firm of Fred Thompson Co., Ltd., has recently constructed a new three-storey and basement brick building to take care of their increasing business. This firm is manufacturing all kinds of electrical supplies; the new location is at 9 St. Genevieve St., Montreal.

To Conserve Fuel.—In order to assist in the conservation of fuel the Grand Trunk Railway are considering the installation of a powdered fuel system in their shops at Point St. Charles. The problem has been carefully gone into by the officials, but final decision has not yet been made.

The New Brunswick Power Co. has during the past year made extensive additions to its plant, $72,112 being spent on power house, $14,543 on new railway equipment, and $11,803 for replacement of special work. In addition to this $24,477 was spent on additions and extensions in the electric and gas departments.

The Geo. F. Foss Machinery & Supply Co., Ltd., has been incorporated at Montreal, to do business as engineers and engine manufacturers, general contractors, bridge builders, boiler makers, machinists, tool makers, etc. Letters were granted to G. Davenport, L. Delarge, L. Potvin, J. Bernier, A. David.

Calgary, Alta.—It is understood that no more hard coal is to be permitted to be shipped into the Canadian West. Winnipeg will receive a small supply, but western points must depend upon the domestic supply. This decision is said to have been reached at a conference between Western coal operators and Fuel Control officials at Ottawa recently.

The Canadian National Carbon Co., Ltd., has been incorporated at Toronto, to deal in calcium carbide, and all gas producing materials and gas, especially acetylene gas, and machinery, etc., for purposes relating to the process. The incorporators are: H. Harrison, barrister-at-law, R. E. Laidlaw, W. Robertson and S. D. Gardiner, students-at-law, and J. F. Van-Lane, accountant, all of the City of Toronto.

New Incorporations. — Joint stock companies incorporated include the following: Zimmerman Manufacturing Company, Limited, Hamilton, capital $1,000,000; Perfection Manufacturing Company, Limited, Montreal, capital $100,000; Webster Motors, Limited, Sherbrooke, capital $75,000; the Perfect Shoe Company, Limited, Montreal, capital $50,000; Prest-o-lite Company of Canada, Limited, Toronto, capital $800,000; Homes Foundry Company, Limited, Sarnia, capital $500,000.

Trenton.—Trenton ratepayers endorsed two money bylaws, one for $16,000 to install modern fire-fighting apparatus, including a new motor fire engine and chemical extinguisher, the other for $21,000 to purchase a waterworks system from the Hydro-Electric Commission of Ontario, who acquired it from Seymour Power and Light Co., when that concern was absorbed by the Hydro. Both bylaws were carried by large majority in heaviest poll ever registered on money bylaws in Trenton.

Montreal, Que.—To aid fuel conservation the Bell Telephone Co. intend to make some changes in their power plant at the head offices in Montreal during the early summer. A steam turbine will be installed to operate the pumps that generate the power for the hydraulic elevators; one of these will be changed over to be run by electric power. Their electrical power is now generated by Robb horizontal steam engines; these are to be replaced by motors, belt connected to the generators.

Crane, Ltd. is the name taken in incorporating at Montreal a company to manufacture, merchandise, buy, sell and in every manner deal in and with all kinds of steam, gas, water, oil, mine, mill, foctory engineers; plumbers; railways, hardware and builders' supplies and materials of all kinds and agricultural machinery and supplies, and to carry on a general engineering business. The incorporators are E. G. Bennett, A. B. Wright, C. Arnold, A. Charers and A. Mathieu.

Conserve Natural Gas for Domestic Uses.—After hearing W. R. Nickle, a Government expert, explain the natural gas situation in Western Ontario, more than forty manufacturers of Windsor and adjacent border cities passed resolutions endorsing the Government's plan to conserve natural gas for domestic consumers by cutting off factories from the supply. It was decided, however, to send a

recommendation to the Ontario Railway and Municipal Board to allow manufacturers the use of gas in small quantities for certain processes until a supply of artificial gas is available.

Chatham, Ont.—A census of the Hydro power users in Chatham is being made by the Public Utilities Commission to ascertain just what power is being used and what might be wanted if there was an increase possible. A record is being made of the product of the various companies and other details connected with the plants. It is reported that similar reports are being compiled in other Western Ontario towns and cities and it is presumed the report will have some connection with the requests being made for more power, because of the order cutting off natural gas on July 1 next.

Price Bros. & Co. Develop Plants.—Sir William Price, president of Price Bros. & Co., in his report states that a new unit was added to the Kenogami mill during the year, bringing the capacity up to 200 tons of newsprint a day, while the Shipshaw Power development was also completed and is supplying the company with 10,000 h.p. The development includes a storage dam with a capacity of nearly seven billion cubic feet. As to general conditions, the president says: "The pulp and paper branches of the business have been somewhat hampered in their operations and supplies, and difficulties experienced in procuring necessary transportation for the finished product."

Shipments of Coal to Canada Restricted.—Plans for the restriction of the movement of anthracite coal from the United States to Canada during the present year have been formulated by the United States Fuel Administration in co-operation with the Fuel Controller of Canada. A representative of the former attended a recent conference of representatives of coal operators, coal miners and railways in Canada, at which this problem was discussed. The conference reached an agreement as to the movement of anthracite coal into Canada, embracing the following: Anthracite coal supplies to points in Western Canada will be materially restricted during the present coal year. No American anthracite will be available for shipment to points west of Winnipeg.

Regina, Sask.—The City Commissioners have been authorized to endeavor to arrange a thirty-day option on the $175,000 electric light unit which the council has been asked to purchase to ensure a sufficient supply of energy to meet the anticipated demands of the coming winter. The city has received offers of two American machines, one of which is ready for immediate delivery, consisting of a General Electric Co. turbine and a Westinghouse condenser, and the other, which will be ready for delivery about September, consisting of a Westinghouse turbine and a Wheeler condenser. The price of the two units is within $2,000 of the same figure. The officials reported that they would sooner have had a combination of one of the turbines with the other condenser, but

The Rising Cost of Power

There has been a big jump in the cost of coal and labor—in everything concerned in the generation of power. How much of your power are you wasting by allowing scale to form on the boilers?

DIXON'S PIONEER BOILER GRAPHITE

is one of the safest, simplest and most effective scale treatments known. It makes the scale soft and easy to remove, protects the metal and can be used with any feed water and in any type of boiler.

Dixon's Pioneer Boiler Graphite will help you lower your power costs.

TORONTO

NON-CORROSIVE CYLINDER OIL

MANUFACTURED ONLY BY E. H. KELLOGG & CO. NOS. 242 & 244 SOUTH ST. NEW YORK, U.S.A.

FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.

"Clean All" Feed WaterTreatment

Your Boiler Troubles are Solved and the Solution is Genuine.

We guarantee that "Clean All" if used according to directions:

To remove (not dissolve) scale already formed, and to stop further formation.

To stop pitting, corrosion and minor leaks.

To be absolutely harmless to metals, packings and fittings.

To remove oil and grease, and increase efficiency of boilers 100%.

Submit samples of water used and all particulars of conditions of boilers, etc., and let boiler specialists diagnose your case.

SOLD IN 30 or 50 GALLON LOTS UNDER 60-DAY TRIAL.

the owner of the equipment would not consider this proposal.

To Develop Peat.—In this week's "Gazette" announcement is made of the incorporation of the National Peat, Limited, with a capital of $100,000. The purposes of the company, as set forth in its charter, are: to carry on the business of treating, refining, concentrating, mining, excavating, reducing, precipitating, analyzing, manufacturing, buying and selling peat and all by-products thereof. The provisional directors of the company are: Edward Lindsey Middleton, Albert Edward Knox, Frances Morrow, Thomas Louis Monahan and Florina Berrini.

Walkerton.—Tenders will be received by the undersigned up to the 25th day of May instant, inclusive, for the construction of a concrete dam between 180 and 210 feet long, to replace the Saugeen Electric Light and Power Co,. Ltd., former wooden dam across part of the Saugeen River on the Company's mill property at Southampton, to connect with the concrete dam already erected thereon, and for the doing of certain excavation, filling and other work connected therewith. Plans and specifications may be seen at the Company's office at Walkerton, Ontario.

CATALOGUES

Metlskin Boiler Preservative.—A folder giving particulars of the Metlskin boiler preservative manufactured by the Metlskin Co. of Rochester, N.Y. The Canadian Fairbanks-Morse Co. are the Canadian distributors.

What It Means To You is the title of a bulletin being distributed to the trade by the Dodge Manufacturing Co., Toronto. The bulletin deals with the principal features of the Dodge standard wood split-pulleys and contains an illustration showing their construction. The bulletin contains a list of firms in Ontario who stock the Dodge transmission equipment.

The Link-Belt Co., Chicago, Ill., has recently distributed a new publication, No. 359, entitled "Chain Driven Motor Trucks and Tractors." The bulletin describes in detail the principal features and advantages of the Link-Belt chain-drive. It also contains particulars of the chain and a number of illustrations of tractors and trucks equipped with the chain drive.

Pumps for Any Service is the title of an 84 page catalogue just issued by Darling Brothers Ltd., engineers and steam specialists, 120 Prince street, Montreal. It describes in detail, both in illustrations and text, the many and varied lines of pumps and compressors manufactured by this firm. It also contains several pages dealing with important information for the benefit of intending purchasers of pumps. The book is well gotten up and is a credit to Darling Bros.

Power-Driven Air Compressors.—The Canadian Ingersoll-Rand Co., Ltd., Montreal, has issued recently bulletin K-301-A, describing two-stage, power-driven air compressors, of the duplex type, "PLB-2." This is a 16-page 6 x 9 pamphlet outlining notable features of construction, such as the "Circo" leaf valves, Haight 100 per cent. belt wheel joint, bath lubrication system, dust-proof frames and casings, etc., as well as the marked compactness of the design, yet easy accessibility of all parts.

Bakelite Micarta Gears.—Technical information regarding Bakelite Micarta D gears is contained in a pamphlet, A-2132, recently published by the Westinghouse Electric and Manufacturing Co. of East Pittsburgh. The distinctive features of this material for noiseless gears and pinions are listed together with its physical properties. Methods of turning and drilling and gear cutting are described and illustrated with many half-tones and drawings. Methods of attaching to the driving shaft, which have proved suitable for gears of all sizes, are shown, and tables of pitch, teeth and other gear data are also given. There are formulas for the horse-power rating, the amount of power which can be transmitted through press fit and for calculating other variables in gear practice. The book, which is of twelve pages, is a valuable addition to the library of anyone who has to do with noiseless gears. It will be sent on request to the company's nearest office.

CANADA SECURES ORDER FOR CABLES FOR AUSTRALIAN GOVERNMENT

As a result of the efforts of Mr. D. H. Ross, Canadian Trade Commissioner in Melbourne, Australia, the Eugene F. Phillips Electrical Works, Limited, of Montreal, have received a contract for about 1,000,000 feet of insulated lead-covered telephone cable, required by the Post Office Department of the Government of Australia.

Duplex Boiler Feeders

Feed Condensation directly into high-pressure or low-pressure boiler, eliminating receiving tanks.

Saves floor space, piping, valves, boiler feed pumps, etc.

Saves 75% of steam required by pumps.
Feeds hotter water than a pump can handle.
Packless swing joints.
No load on swing joints.
Tested to 350 lbs.

Hundreds of these machines are feeding boilers at temperatures over 300 degrees.

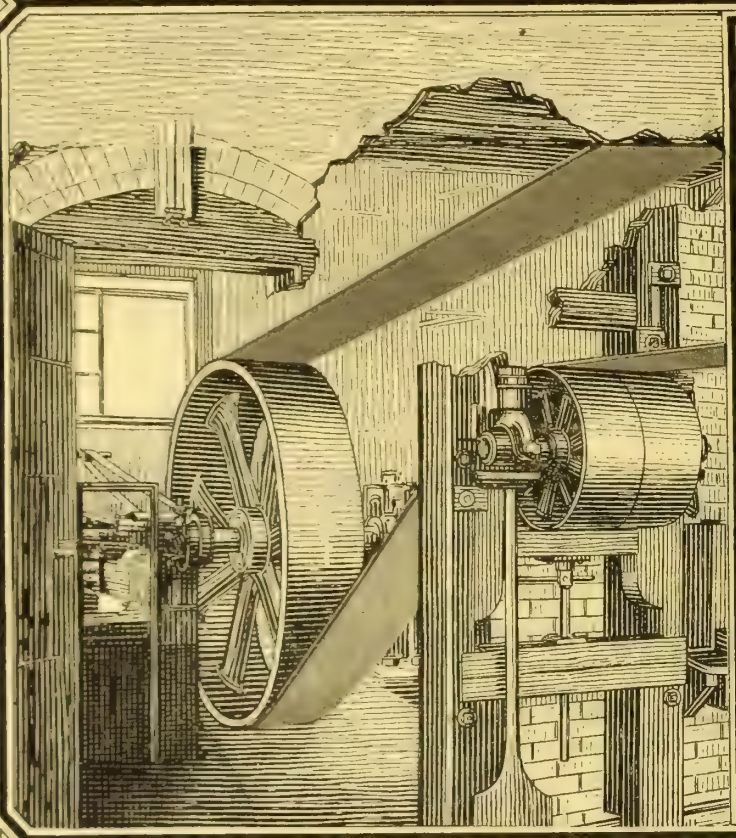
Standardized Series

LEATHER BELTING

Tanned by us for belting use



47 Years of Service

20-inch and 26-inch Graton & Knight double belts in plant of A. G. Dewey Co., Quechee, Vt., the oldest satinet mill in the U.S. and the largest in the world.

ONE of these belts was installed in 1870 and the other in 1880. Both are still running, after an average of 42 years of service. Both give evidence of many future years of efficient work.

One of them has travelled ten hours a day continuously, a total of 3,250,000 Miles, and has never needed repair.

Fifty years ago, Graton & Knight Leather Belts were made to the highest standards then attainable. To-day their quality is actually better.

Write for information about Standardization as applied to Belting.

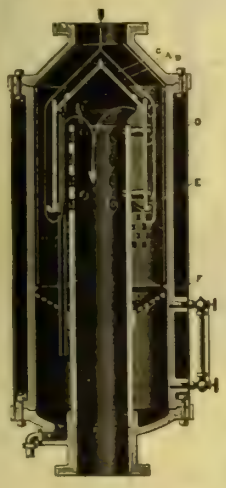
III IMPORTANT THINGS
TO CONSIDER ABOUT A SEPARATOR.



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

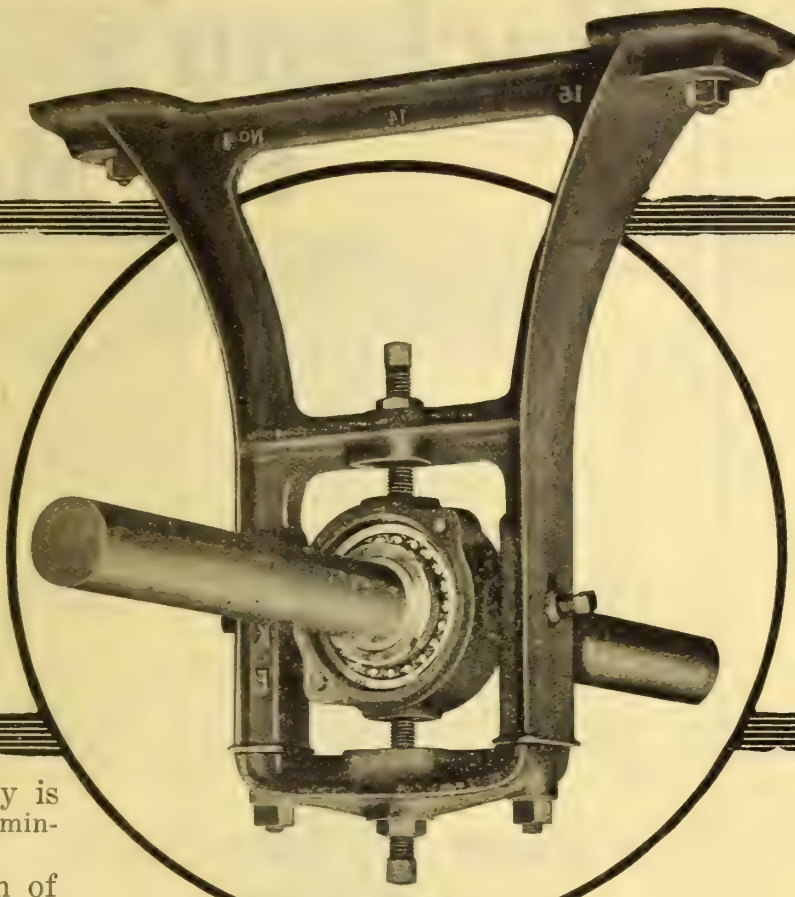
Supporting the Line of Industry



The industrial problem of the day is how to save power and conserve the diminishing fuel supply.

Transmission losses due to friction of plain bearings amount to from 20% to 40% of the total power used in the plant.

SKF Ball Bearing Hangers will reduce these losses over 33%. This saving alone will make their installation a profitable investment. Then, too, the lubricant savings and the impossibility of hot bearings is an item to consider.

We have a special catalog describing their use in your line of business. Send for a copy.

MacLean's Magazine For MAY

Canada at the Peace Conference

THE British Empire will have a representative or representatives at the Peace Conference. The question is—Who? Who will be Canada's choice? Will Canada have any part in that conference of momentous import? H. G. Wells, one of the greatest writers of the age, has written on the subject of who is to represent the Empire at the Peace Conference. He has written this article for MACLEAN'S MAGAZINE and it appears in the May issue. (Mr. Wells parcelled this manuscript and addressed it himself, for MACLEAN'S MAGAZINE.)

How Does a Retreating Army Behave?

GEORGE EUSTACE PEARSON tells how in the May MACLEAN'S. Mr. Pearson is a Princess Pat man, and was gassed at St. Julien. He is now lecturing for the American Government in Texas and elsewhere. He is a Toronto man, and his war stories are of sensational interest. The **Saturday Evening Post** has published two of his stories, and other American magazines will. Mr. Pearson is well known to readers of MACLEAN'S MAGAZINE, and this wonderful contribution to the May MACLEAN'S will be read with intensest interest. Mr. Pearson is a wonderful delineator of war.

Robert W. Service in the May Number

Service is perhaps Canada's best known poet. He is at the front, and ever since going there two years ago his verse has been appearing in MACLEAN'S MAGAZINE—a fine compliment to Canada and MACLEAN'S. In the May number he has a stirring ballad—"The Twa Jocks"—great stuff!

Stephen Leacock is There, Too

Mr. Leacock likes MACLEAN'S. He is loyal to Canada. He gives to the Canadian people the children of his fancy—and he makes this gift through MACLEAN'S MAGAZINE. "May-time in Mariposa" is his contribution to the May MACLEAN'S. Lou Skuce illustrates it.

A. C. Allenson has a Story

MR. ALLENSON is another Canadian whom the editors of American magazines appreciate, and show their appreciation by buying his stories. Mr. Allenson remains loyal to MACLEAN'S which has been his cradle, as it were. We rejoice to be able to say that we shall have many stories from this Canadian short-story writer. His story in the May MACLEAN'S is "Drop Behind and Lose Two"—amusing and tender. W. B. King, a Saturday Evening Post illustrator, has made the drawings that accompany Mr. Allenson's story.

The Departments Everybody Likes

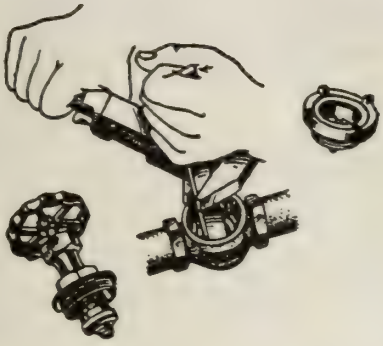
MACLEAN'S MAGAZINE is liked by many because it has an admirable **Review of Reviews Department.** This department condenses for busyreaders the best things appearing in the leading magazines and reviews of Great Britain and the United States. * * * **Women and Their Work** is a department that satisfies women. Women are bearing so many of the world's burdens nowadays that their fields of endeavor and interest deserve the recognition which they receive in MACLEAN'S. * * * **The Business Outlook, The Investment Situation** and **The Nation's Business** are departments valued by the business man.

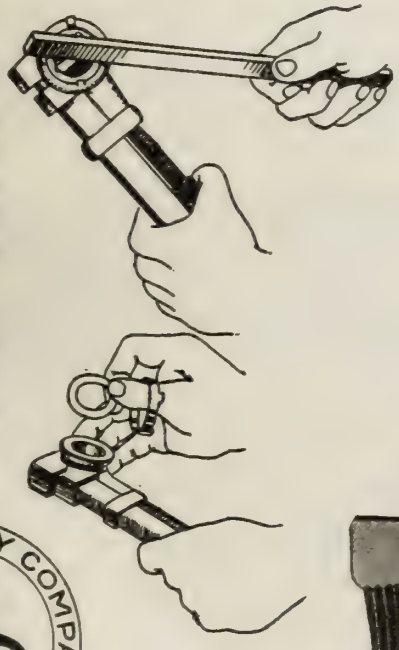
(Circulation of MACLEAN'S is now 60,000—10,000 more than it was six months ago.)

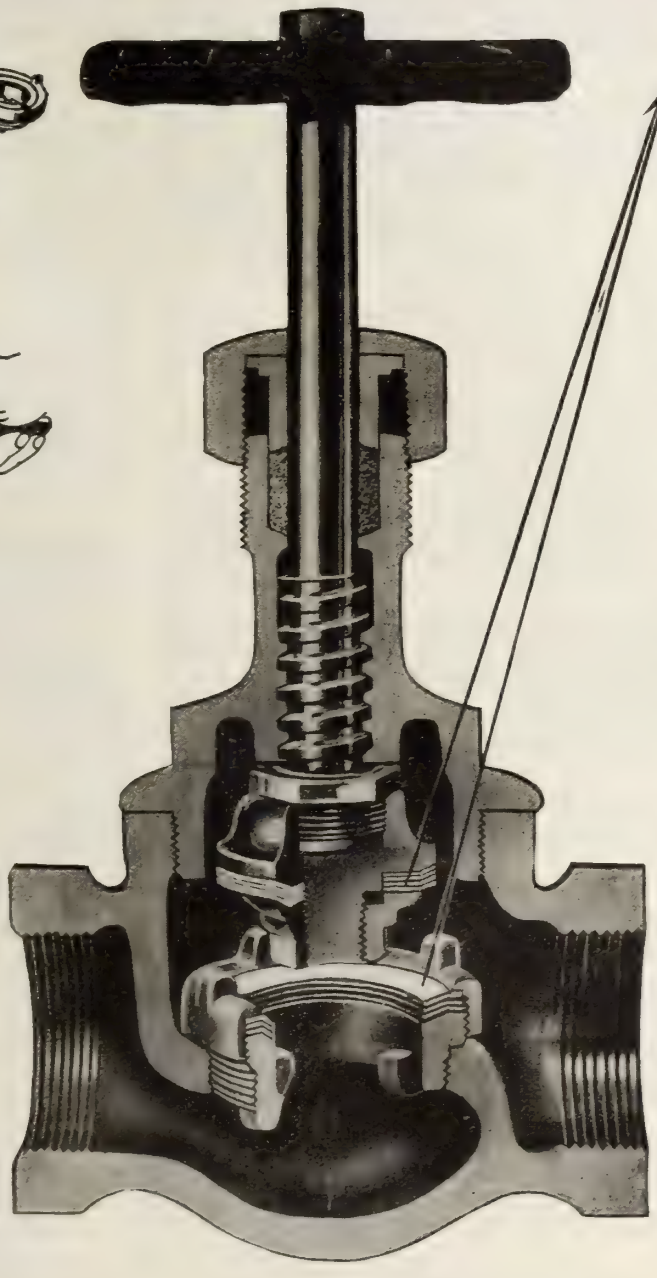
At All News Dealers : : 20c.

MULTIPLATE

"Valve Service"







By this method you do not take the valve out of the pipe line.

To remove plates see cuts opposite.

Note These Plates

When the valve leaks, simply take off the first pair of plates and throw them away; tighten up the other parts, and the valve is as good as new. This can be done till the plates are used up, then re-fill with new plates. No grinding.

Becoming a Bigger Man

WHAT is the difference between some men you know and others known to you? Why are some men earning $3,000 a year and some $30,000? You can't put it down to heredity or better early opportunities, or even better education. What, then, is the explanation of the stagnation of some men and the elevation and progress of others?

We are reminded of a story. A railroad man, born in Canada, was revisiting his home town on the St. Lawrence River. He wandered up to a group of old-timers who sat in the sun basking in blissful idleness. "Charlie," said one of the old men, "they tell me you are getting $20,000 a year." "Something like that," said Charlie. "Well, all I've got to say, Charlie, is that you're not worth it."

A salary of $20,000 a year to these do-nothing men was incredible. Not one of the group had ever made as much as $2,000 a year, and each man in the company felt that he was a mighty good man.

Charlie had left the old home town when he was a lad. He had got into the mill of bigger things. He developed to be a good man, a better man, the best man for certain work. His specialized education, joined to his own energy and labor sent him up, up, up. To put it in another way: Charlie had always more to sell, and the world wanted his merchandise—brain, skill and ability. Having more to sell all the time, he got more pay all the time.

Charlie could have stayed in the old home town; could have stagnated like others; could have been content with common wages. In short, Charlie could have stayed with the common crowd at the foot of the ladder. But Charlie improved himself and pushed himself, and this type of man the Goddess of Fortune likes to take by the hand and lead onward and upward.

Almost any man can climb higher if he really wants to try. None but himself will hold him back. As a matter of fact, the world applauds and helps those who try to climb the ladder that reaches towards the stars.

The bank manager in an obscure branch in a village can get out of that bank surely and swiftly, if he makes it clear to his superiors that he is ready for larger service and a larger sphere. The humble retailer can burst the walls of his small store, just as Timothy Eaton did, if he gets the right idea and follows it. It is not a matter of brain or education so much as of purpose joined to energy and labor. The salesman or manager or bookkeeper or secretary can lift himself to a higher plane of service and rewards if he prepares himself diligently for larger work and pay. The small manufacturer, the company director, the broker—all can become enlarged in the nature of their enterprise and in the amount of their income,—by resolutely setting themselves about the task of growing to be bigger-minded men.

Specialized information is the great idea. This is what the world pays handsomely for. And to acquire specialized information is really a simple matter, calling for the purposeful and faithful use of time. This chiefly.

One does not have to stop his ordinary work, or go to a university, or to any school. One can acquire the specialized information in the margin of time which is his own—in the after-hours of business. Which means: If a man will read the right kind of books or publications, and make himself a serious student at home, in his hours—the evening hours or the early morning hours—he can climb to heights of position and pay that will dazzle the inert comrades of his youth or day's work.

IF business—BUSINESS—is your chosen field of work, we counsel you to read each week THE FINANCIAL POST. It will stimulate you mentally. It will challenge you to further studious effort. It will give you glimpses into the world of endeavor occupied by the captains of industry and finance. With the guidance of the POST, and with its wealth of specialized information, you, a purposeful man, aiming to go higher in life and pay, will find yourself becoming enlarged in knowledge and ambition, and will be acquiring the bases and facts of knowledge which become the rungs of the ladder you climb by.

It is the first step which costs. But this cost is trivial—a single dollar. We offer you the POST for four months for a dollar. Surely it is worth a dollar to discover how right we are in our argument. If you have the will to go higher in position and pay, sign the coupon below.

THE MACLEAN PUBLISHING COMPANY, LIMITED,
143-153 University Avenue, Toronto.

Send me THE FINANCIAL POST for four months for one dollar.

Money to be enclosed / remitted.

DAVIS SAFETY

protects you and your plant from the possible boiler explosion that may happen next year, next week or *tomorrow.*

Not only does the Davis Stop and Check Valve protect, but it equalizes the load by making each boiler do its share. Automatieally it will prevent a reserve flow of steam caused by sudden drop of pressure; will equalize the loss by cutting out the laggards; and will close tight when the fire is drawn. Reliable, efficient and absolutely dependable. Visible action—will not stick.

For your free copy of the new Davis Catalog, write the G. M. Davis Regulator Co., 434 Milwaukee Ave., Chicago.

The Check on the Coal Bin

Where radiators are equipped with Dunham Radiator Traps there is a constant, dependable check on the coal bin. The Dunham Radiator Trap saves coal from being wasted. It gets every last bit of heat out of the fuel. It is more than doing its share in helping the Dominion save millions of tons of coal this year.

The Dunham Radiator Trap is a Proved Engineering Success

It is well and favorably known to architects, heating engineers and contractors, and steamfitters all over the country. It is manufactured by a company with an enviable reputation for pioneering the principle now utilized in the best heating systems that engineering skill can produce.

The Dunham Radiator Trap provides an opportunity which no enterprising engineer can afford to overlook—by equipping **coal wasting** heating systems with Dunham Radiator Traps you can convert it into a **coal saving** system.

This means greater heating efficiency at less cost which is a desirable factor in present-day operating expenses.

The Dunham Radiator Trap does away with all annoying adjustment of faulty return devices and air valves (there are no air valves required where Dunham Traps are used).

They save time for the operating engineer.

Write for full information about the Dunham Heating Service and about the Inspection Service we maintain for Heating Engineers, Contractors and Steamfitters.

Morehead
Back to Boiler
SYSTEM

Out of the 600,000,000 tons of coal mined in Canada and United States annually, about ten per cent. of it is needlessly wasted.

Unless you are delivering all the condensation back to the boilers, while it is HOT you are a contributor to this big waste. Coal is too scarce to let this waste continue. The **Morehead Back-to-the-Boiler System** will stop it. It delivers **hot** condensation back to the boiler as pure hot feed water, and thus saves valuable heat units.

The "Morehead System" works automatically, wastelessly, completely. It not only saves fuel it saves boilers and hard work too. Equally controlled temperature in your whole plant, freedom from the troubles of steam pumps, and many other advantages accrue from its use.

Adopt the "Morehead" and help stop a great national waste.

JOHNS-MANVILLE ASBESTOS ROOFING

THIS fire-safe roofing covers a building in the heart of a great city. They used this kind of a roof because there were many stacks like yours all around—stacks belching forth smoke, soot and corrosive fumes.

And just as this Johns-Manville Asbestos Roof is impervious to destructive agents, so will a Johns-Manville Asbestos Roof on your plant be more than a roof covering. It will be a roof protection—safe from communicated fire. And it will be a roof with a minimum upkeep—you don't have to regravel the surface continually. For gravel—heavy, dirt-catching, and retarding the flow of water to the outlets—has no place on a Johns-Manville Roof.

There is a Johns-Manville Asbestos Roofing for every type of service. Ask any branch to tell you all about the one that fits your requirements.

Built-up Roofing for flat roofs. Ready Roofing for sloping roofs. Corrugated Asbestos for skeleton frames.

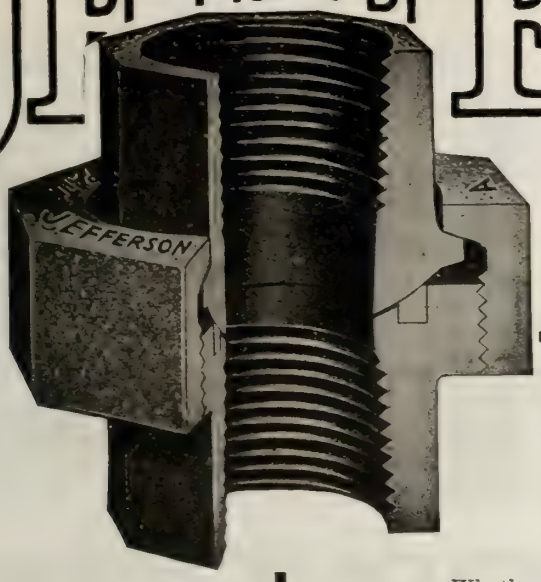
JEFFERSON



Test a Jefferson Union on your Toughest Job

Whether your idea of severe union service is superheat or heavy pressure or corrosive action, you must actually try out a Jefferson before you can realize perfect union service.

Built by specialists, Jefferson Unions embody all qualities necessary for 100% efficiency on pipe line and power plant service. The Jefferson Union is unique in construction because we have protected ourselves with basic patents covering the essential features.

Take the drawn brass seat ring for instance. Now of course, every practical engineer knows that a brass-to-iron joint will not corrode (Point No. 1). But with an all-brass seat the expansion and contraction would be excessive, so in the Jefferson Union we embed the brass seat ring into the malleable iron by exerting enormous pressures—up to 40 tons. The seat ring cannot become dislodged under any conditions. (Point No. 2). Finally the seat ring is ground accurately to fit the spherical face of the other part of the union. This insures a tight joint even though the pipe is slightly out of line. Point No. 3).

And so we could go right along with each Jefferson strong point, but these are all covered in detail in our new Catalog. Send for your copy to-day—we'll tell you where to find the nearest Jefferson Dealer.

JEFFERSON UNION COMPANY

Most Efficient Boiler Feeder

LUNKENHEIMER AUTOMATIC INJECTOR

Will deliver more water per pound of steam and the capacity is diminished in a lesser degree by long lifts and hot feed water than any other Injector made.

This is due to the scientific design of the tubes, which are proportioned for maximum delivery, and it maintains its maximum delivery in service, because the tubes are made of a special **hard bronze** which is peculiarly resistive to the inevitable and severe erosive action of the saturated flow at high velocity. Besides, the Lunkenheimer design of "spill" eliminates the rapid wear of the combining tube.

The wide range of operation of the Lunkenheimer Injector; its instantaneous restarting after a temporary interruption of either the steam or water supply; its durability and the interchangeability of parts, are details which merit the consideration of every user.

Write for descriptive Booklet No. 504 DJ, which contains valuable information on the use and operation of injectors.

MUELLER

Globe and Angle Valves

BUILT from actual, practical experience. Made of the famous *MUELLER* steam metal and fully guaranteed against all defects in design and construction. Not a Valve, but *the* Valve.

¶ *MUELLER* globe and angle Valves can be repacked under pressure. The disc is so designed as to adjust itself to any position and still receive the thrust of the spindle on the center line; thus preventing any distortion to the seat or diaphragm. The pipe threads are full length, and are tapered to conform to I. P. Threads, insuring perfect joints.

¶ Full sized and unobstructed passages guarantee full service. The large Hexagons allow an excellent wrench grip and our design puts the strain where it belongs, so that there is no danger of distorting either the body or the bonnet. Furnished with enameled, Malleable iron wheel handles. Every *MUELLER* Valve tested to beyond unusual service conditions. Write for prices.

MUELLER **gate and check valves, steam cocks, etc. rank highest in every branch of exacting service.**

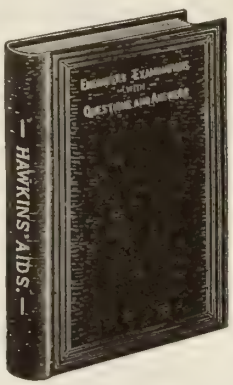
Books for the Engineer's Library

Hawkins' New Catechism of Electricity

It contains 550 pages with 300 illustrations of electrical appliances; it is bound in heavy red leather, with full gold edges and is a most attractive handbook for electricians and engineers. One-third of the book is devoted to the explanation and illustrations of the dynamo, with particular directions relating to its care and management—$2.10 post paid.



Engineers' Examinations

By N. Hawkins, M.E.

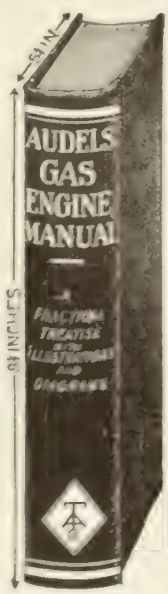
It presents in a condensed form the most approved practice in the care and management of steam boilers, engines, pumps, electrical and refrigerating machines, with examples of how to work the problems relating to the safety valve, strength of boilers and horse power of the steam engine and steam boiler.—$2.10 post paid.

Steam Turbines

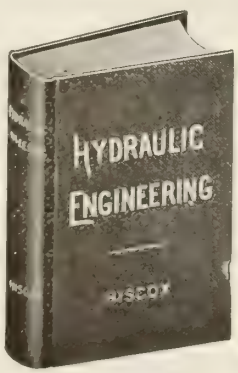
By Leland.

A reference work on the development, advantages and disadvantages of the steam turbine; the design, selection, operation and maintenance of steam turbine plants and turbo-generators. 135 pages. Illustrated.—$1.00.

Audel's Gas Engine Manual



A practical treatise relating to the theory and management of gas, gasoline and oil engines, including chapters on producer gas plants, marine motors and automobile engines.—$2.00.



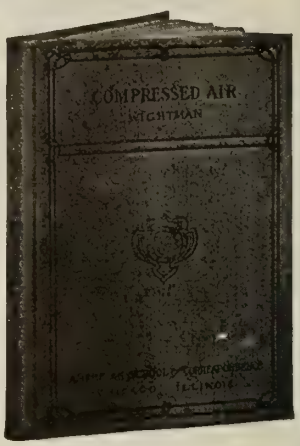
Hydraulic Engineering

By G. D. Hiscox.

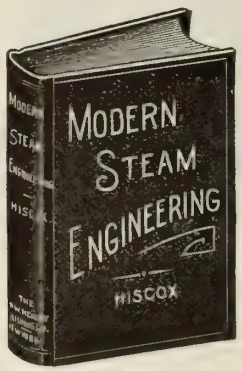
This comprehensive book of Hydraulics written by an experienced engineer, is a practical treatise on the properties, power and resources of water for all purposes, including the measurement of streams, the flow of water in pipes or conduits; the horse-power of falling water; turbine and impact water wheels; wave motors, etc. All who are interested in Water Works Development should have a copy. 320 pages, 305 illustrations. Price $4.15 post paid.

Compressed Air

By L. I. Wightman, E.E.



A reference work on the production, transmission and application of compressed air; the selection, operation and maintenance of compressed air machinery; and the design of air power plants. Illustrated.—$1.10.



Modern Steam Engineering in Theory and Practice

By Hiscox.

This book has been specially prepared for the use of the modern steam engineer, the technical students, and all who desire the latest and most reliable information on steam and steam boilers, the machinery of power, the steam turbine, electric power and lighting plants, etc. 450 pages. 400 detailed engravings.—$3.15 post paid.

Boiler Construction

By Kleinhans.

The only book showing how locomotive boilers are built in modern shops. Shows all types of boilers used; gives details of construction; practical facts, such as line of riveting punches and dies, work done per day, allowance for bending and flanging sheets and other data that means dollars to any railroad man. 421 pages, 324 illustrations, six folding plates.—$3.00.

Compressed Air, Its Production, Uses and Application. *By G. D. Hiscox, M.E.*

Comprising the physical properties of air from a vacuum to its liquid state, its thermodynamics, compression, transmission and uses as a motive power in the operation of stationary and portable machinery, in mining, air tools, air lifts, pumping of water, acids and oils and the numerous applicances in which compressed air is a most convenient and economical transmitter of power.—Price $5.15 post paid.

Boiler Accessories

By Walter S. Leland, S.B.

Assistant Professor of Naval Architecture, Mass. Institute of Technology, American Society Naval Architects and Marine Engineers. 144 pp., 80 illus. Cloth binding. A treatise giving complete descriptions of the various accessories of the boiler room and engine room essential to economical operation, such as evaporators, pumps, feed-water heaters, injectors, mechanical stokers, etc., with practical instruction in their use.—Price $1.10 post paid.

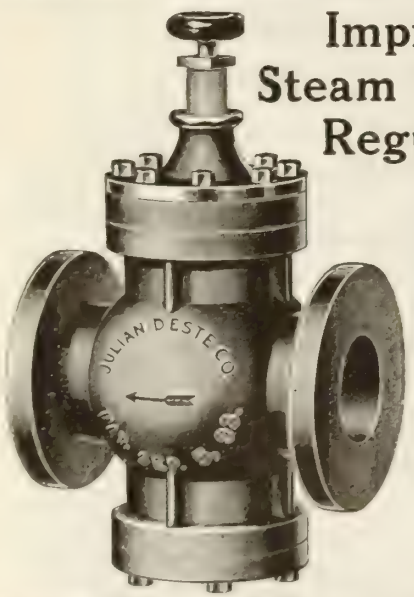
Improved Steam Pressure Regulator



For Universal Application to all the varied and various conditions under which a reduced pressure of steam, water or other fluid is required, this Regulator (see illustration) has no equal. It is compact and self-contained, without levers, weights or projections.

No glands or packing; no drip or leak of steam or water. Suitable for any boiler pressure; made entirely of metal; is a lock valve, very simple and sensitive.

The universality of use of this Regulator is one of its best features, but it is in Steam Heating that its use is most common and obvious. Send for leaflet fully descriptive of this Regulator (contains price list) to the manufacturers.

STANDS FOR

D. K. McLAREN'S

BRITISH-OAK-TANNED
FLAWLESS BACK LEATHER

THIS OAK LEAF has been a guide to efficient and economical belt service for years to many of Canada's prominent industrial power plants.

Every D. K. McLaren Belt has the Oak Leaf Stamped plainly upon it. Let this trade mark guide you as it is guiding others to satisfactory belting service.

Minimum stretch, minimum slippage and fewer breaks are the results you can expect from the adoption of D. K. McLaren *British-Oak-Tanned* Belts.

GET IN TOUCH WITH SOME USERS. Just fill out the coupon below and we'll gladly furnish you with some names.

BACK LEATHERS—This is the best portion of the hide for belting purposes. Every inch of D. K. McLaren Belts represents Flawless Backs of the hides of the choicest steers.

BRITISH-OAK-TANNED—The most approved process known for preparing belts for hard service. Every bit of the hide's natural strength is preserved in D. K. McLaren's belts by the expert use of this famous process.

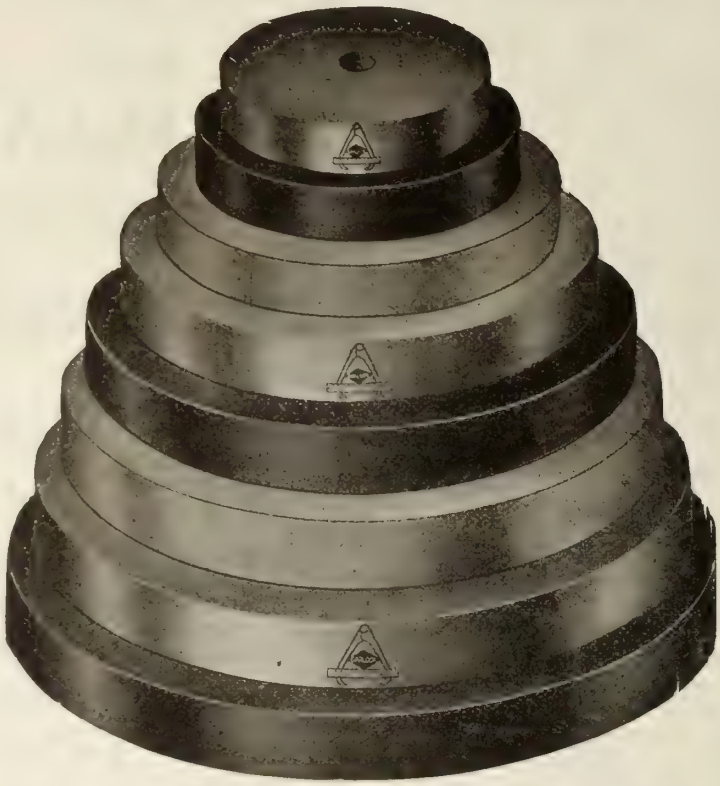
GARLOCK

PUMP VALVES



The service of pump valves depends upon the compounds as well as the consistency and cure of the valves. The compounds used in Garlock pump valves have been established after years of trial in actual service and under the most severe conditions. Pump valves should always be used for the purposes for which they are intended. The following are a few of our leading styles and grades of valves:

Style	No.	139—For medium pressure cold water
"	"	175—For high pressure cold water
"	"	182—For warm or greasy water
"	"	108—For hot water
"	"	105—For boiling water
"	"	154—For air compressors and condensers

We guarantee our pump valves to give satisfactory service when used under conditions for which they are intended.

ALEXANDRIA, ONTARIO

Dont Claim Exemption

—because the air is filled with dust,
—because this dust settles on the belts,
—because it makes a belt dressing "ball up"
are no reasons at all why your belts can't have the benefit of

CLING-SURFACE Belt Preservative

Just wipe the dust off first.

Then with the swab (as shown) treat the face of the belts **a little at a time.**

Your belts will absorb CLING-SURFACE very quickly, leaving a clean, **not sticky,** surface.

It will be smooth, velvety, and will not slip.

Nor will it hold the dust.

Your drives will last longer, do more work, cause no trouble, and can be run easy or slack under full loads.

They will never again have static electricity.

* * *

Results like these PAY.

Are you willing to try this treatment if such trial **costs you nothing?**

Then write to-day for the 25-pound can we have waiting for you.

Use it sixty days.

If you're satisfied, pay us for it. If not, we will take back what you have left, charge you nothing for what you've used, and pay the freight both ways.

ALL CHEERFULLY—no hard feelings!

Remember, use CLING-SURFACE and you won't need belt dressings.

WILL NEVER NEED RENEWING

ORIENTAL BREWING AND ICE COMPANY,
Manila, P.I.

Febr. 16, 1917.

Magnolia Metal Co.,

Gentlemen,—A little over 9 years ago I was sent from Chicago to Hongkong, China, to install all the machinery in a modern brewery and ice plant—all power used in brewery and bottling shop being furnished by two 40 K.W. D.C. 220 Volt Generators direct connected to high speed engines running at 360 R.P.M. Trouble was encountered at once with the outboard bearings heating up excessively, and as the lead was gradually increased it became necessary to change Generators every two hours. The best Oil that money could buy did not remedy the trouble. After exhausting my patience our Manager at last consented to buy me enough Magnolia Metal so I could reline the troublesome bearings.

This is now nine years ago. I had no lathe in which to turn up the new bearings and had to scrape them to fit. These two units were in constant operation in China for six years. They were then dismantled, sold and shipped to Manila, where they are installed in the Oriental Brewery & Ice Co. They are running with a heavy overload as high as 60% for hours at the time. During all these years the bearings lined with Magnolia Metal have never at any time given the least bit of trouble, and from all indications they will never need renewing during the rest of these units useful life.

Yours very sincerely,
M. LAUVITSEN,
Chief Engineer.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914 With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID, Minister of Public Works and Highways

W. A. RIDDELL, M.A. Ph.D., Supt. Trades & Labour Branch

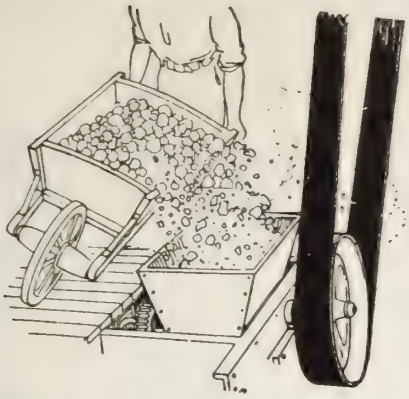
Plan of "Bennis" Coal Bunker with Elevator feeding a "Bennis" Stoker

Plants similar to the above have been installed in many of the new National Factories to ensure maximum output and rapid and efficient handling with the minimum of labour. "Bennis" Conveyors and Elevators are indispensable for the cheap and efficient transport of material in bulk. Schemes prepared to any requirements.

Write to-day for descriptive literature.

ED. BENNIS & CO., LTD.

Little Hulton, Bolton; 28 Victoria Street, S.W. London, Eng.



SCANDINAVIA BELTING

Is a Good Belt for Dusty Places

In cement plants and brick plants where there is lots of dust this belt is producing results that are very satisfactory for the mill operators.

You know how wearing grit is on a belt, and you want a belt that will not come apart when only partly worn through.

"Scandinavia" is this kind of a belt—there are no plies to come apart—it is solid woven. We have seen these belts still giving good service when the thickness was half worn through, and on the pulley side of the belt there were no frayed ends—the surface of the belt was smooth.

Mr. Plant Manager, you know what this means. If you require a belt for operating in a dusty place let us ship you one, please. It will be a pleasure to us both.

NOTE.—Do not use "bar" or "stick" belt dressing on textile belts.

Federal Engineering Co., Limited

172 John Street, Toronto

Oil is Too Expensive to be Wasted

Think of the price of oil to-day—and over half the oil you buy is wasted—lost on the floors, rags and waste.

Anderson Pressure Oil Filters

WILL ELIMINATE THIS WASTE.

It is simply a matter of collecting it in drip pans, properly located beneath the engine or machinery. After passing through the Anderson Filter it can be used over again for lubricating purposes on the finest bearings until actually consumed.

The Anderson Filter is the only one which treats the oil with the refiners process and is therefore the only filter which can deliver the oil just as clean and pure as the new oil you purchase.

Our catalogue gives full details. Drop a line for it now.

Canadian Association of Stationary Engineers

Incorporated May, 1887 Incorporated at Ottawa, June, 1917

An organization having as its aims and objects:—

To promote the knowledge of its members in the art and science of Steam Engineering.

The dissemination of information beneficial to the members of the association in the discharge of their calling.

To further and protect the interests of competent engineers, and receive such as members of this organization.

To secure, through proper legislation, the greatest security in operation of steam plants.

To assist unemployed members to secure positions.

To maintain freedom of action between employer and employee.

The members of the Association subscribe to the above in the full belief that ability and knowledge of one's profession are necessary to insure the highest degree of success.

Labor Study Energy

These three essentials have been responsible for the success of the world's greatest men. They are no less essentiál for yours. We cannot all become great, but this fact does not lessen the necessity for the exercise of these essentials in our individual occupations. Cool, calm, calculating judgment characterizes the successful power house operator of to-day. The demands on the engineer of to-day are many, and the obstacles in his path are great. To assist in the overcoming of these and help the accomplishment of great works, material, moral and educational, is the desire of all our members.

The benefits accruing from association with members of his fraternity, the opportunity to benefit by their experience, and the inspiration to greater effort by reason of their success render membership in this association indispensable to all progressive engineers.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

J. H. HALE, General Secretary, C.A.S.E.

OIL FILTRATION EFFICIENCY

The efficiency of any Oil Filtering and Circulating System is measured by the saving which it effects in oil and labor, in addition to reducing friction to an absolute minimum. This in turn depends on the capacity of the System to remove from the circulating oil, all foreign matter which causes friction, performing these operations with the least possible attention and little or no "upkeep." The ability of the System to do this depends on the efficiency of the clarifying and filtering devices.

In a

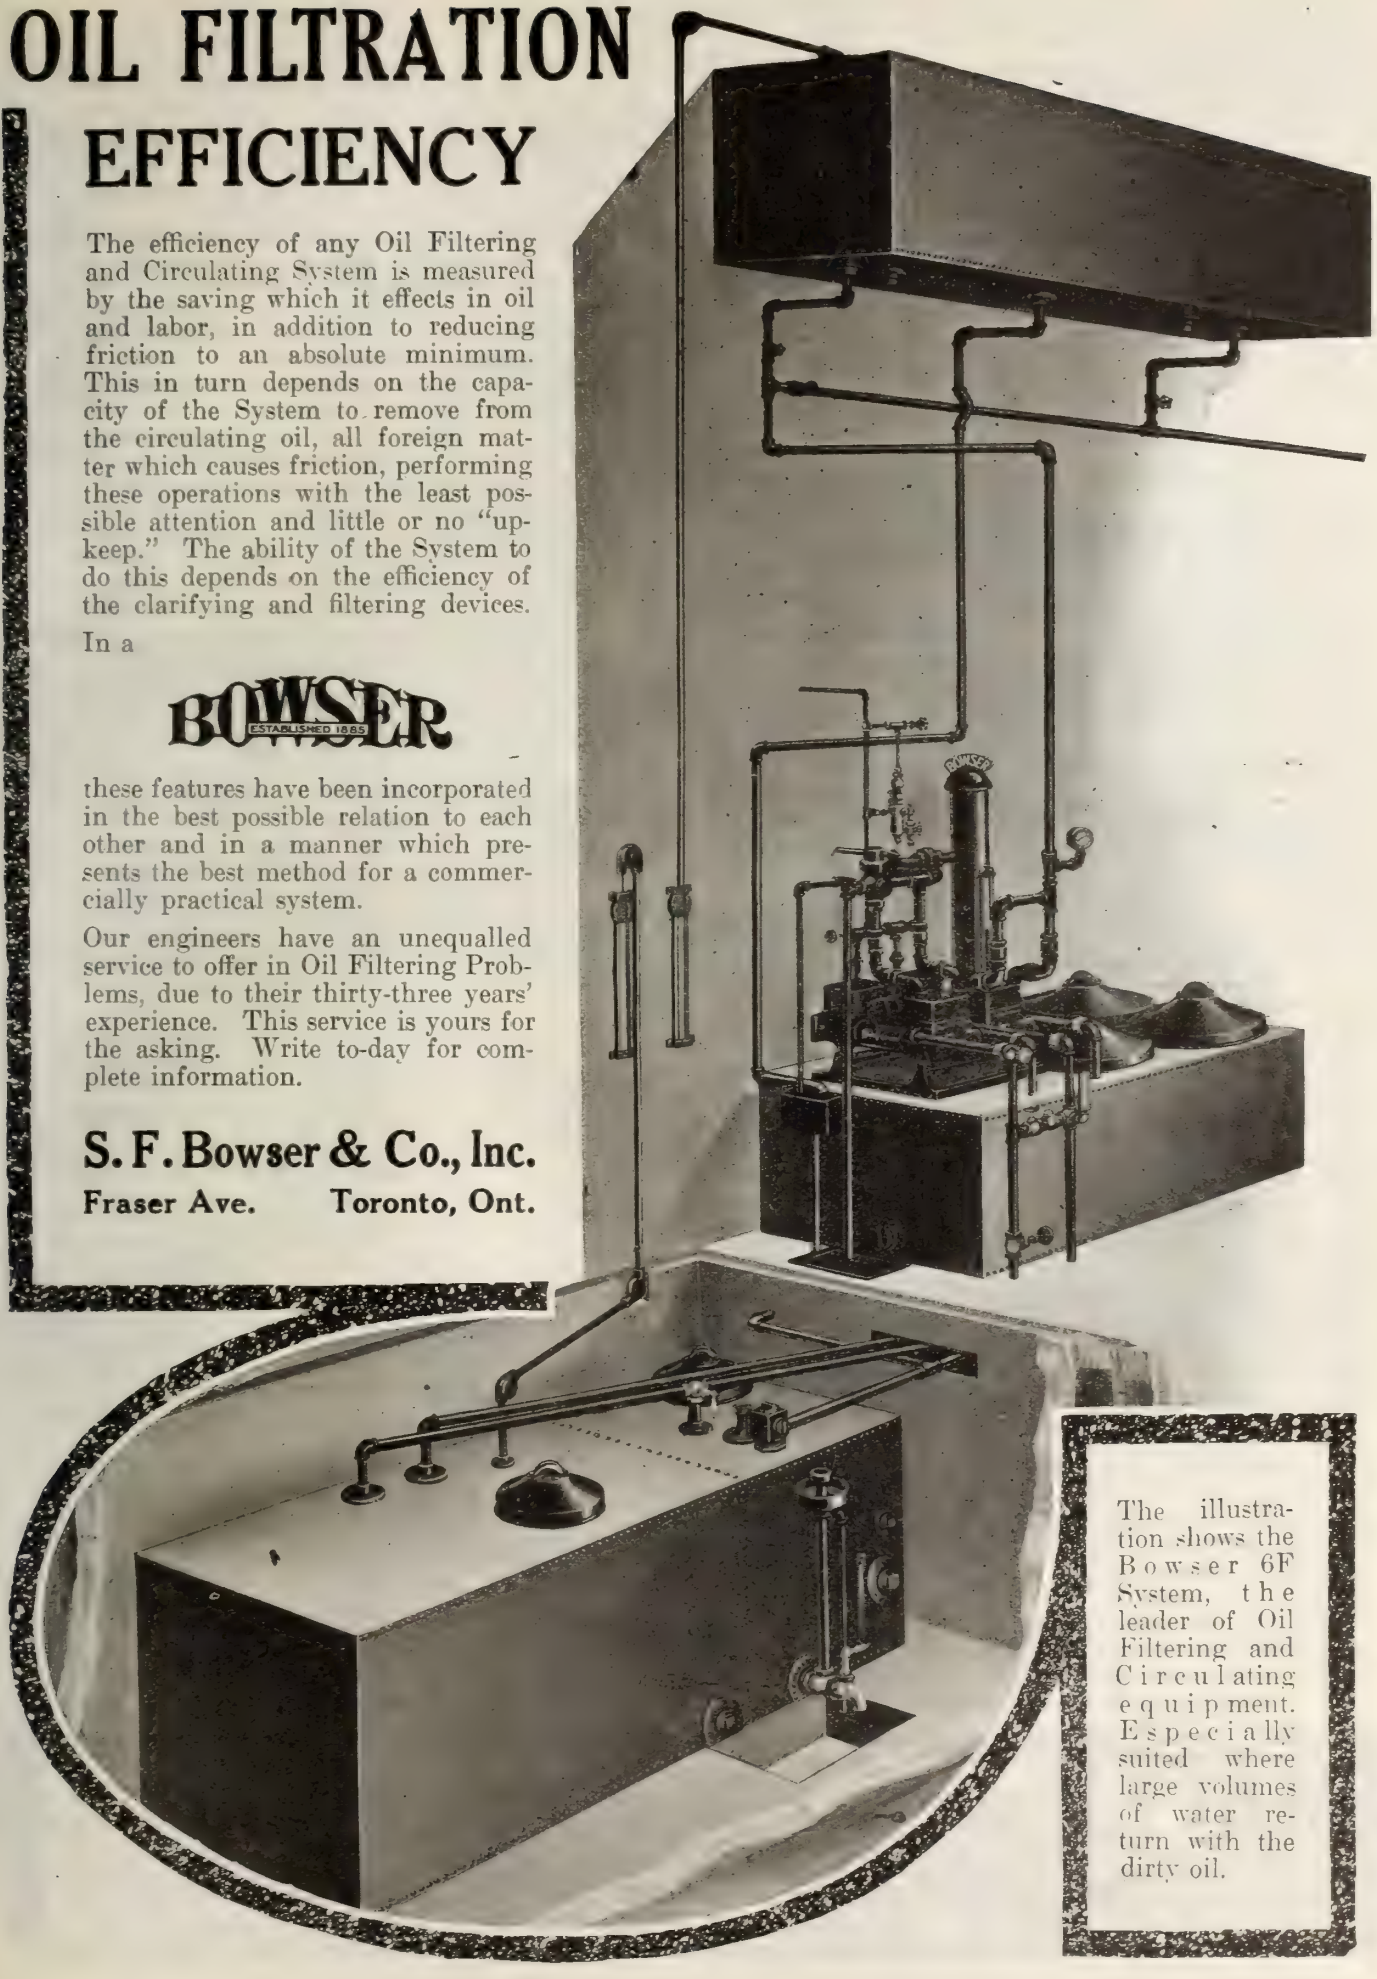
BOWSER
ESTABLISHED 1885

these features have been incorporated in the best possible relation to each other and in a manner which presents the best method for a commercially practical system.

Our engineers have an unequalled service to offer in Oil Filtering Problems, due to their thirty-three years' experience. This service is yours for the asking. Write to-day for complete information.

S. F. Bowser & Co., Inc.

Fraser Ave. Toronto, Ont.



The illustration shows the Bowser 6F System, the leader of Oil Filtering and Circulating equipment. Especially suited where large volumes of water return with the dirty oil.

Don't buy that New Electrical Apparatus Just Yet

WE can supply you with high-grade apparatus that has been slightly used and discarded through no fault of its own, at an immense saving in cost. For instance, in many cases we take over entire plants simply because of changed conditions such as increased capacity, change of system, etc.

EVERYTHING IS OVERHAULED AND REFINISHED BY US AND **GUARANTEED** AS GOOD AS NEW, BOTH ELECTRICALLY AND MECHANICALLY.

Our catalogs of offerings should be in the hands of every power plant superintendent each time they are gotten out, and it will be worth while for anyone interested in this class of power plant equipment to be on our mailing list to receive all offerings.

Nearly all of the principal power, lighting and street railway plants in the United States are our customers.

WRITE FOR OUR LATEST CATALOG of Power House Equipment, Street Cars, Motors, Hoists, Compressors, etc.

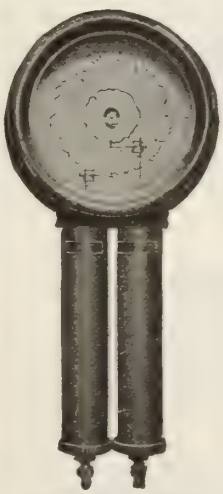
UEHLING WASTE METER

COMBINED

CO_2 AND TEMPERATURE RECORDER



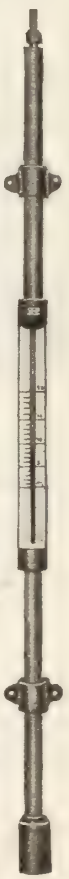
Record of CO_2 and stack temperature on one chart.

Does your fireman know how much fuel he is wasting? Do you know?

The Uehling CO_2 Recorder makes a complete 24 hr. record of your combustion efficiency and the CO_2 indicator at the Boiler Front holds the fireman responsible.

Get more **Steam** per pound of **Coal** and reduce your annual fuel consumption.

Let us know the number and size of your boilers and coal consumed per year, upon receipt of which information we will be glad to send you full particulars.



CO_2 Indicator for Boiler Front

Let us hear from you. We are pioneers in the manufacture of Indicators and Recorders for Power Plant purposes.

Send for our Bulletin No. 110.

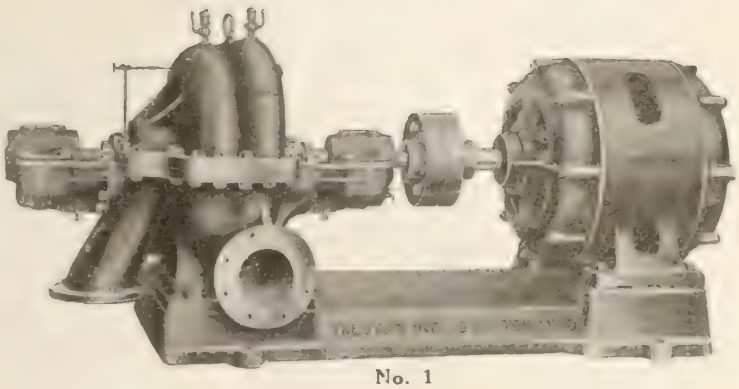
Inglis Pumps

INGLIS TURBINE PUMPS set the standard of merit and efficiency. Numerous installations throughout Canada testify daily to their reliable performance under the most severe strains.



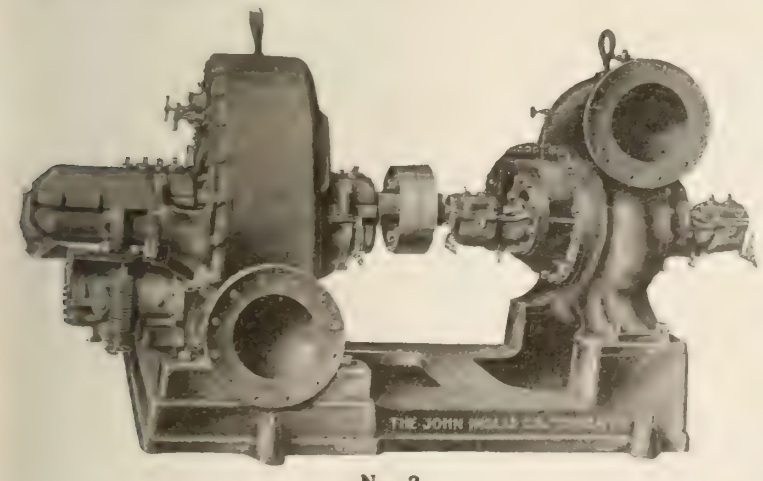
No. 1

Oil ring bearings, hydraulic balance and water-cooled thrust bearings are standard for all "Inglis" Turbine Pumps.

Impellers and passages are highly finished, all working elements being carefully balanced against vibration.

Illustration No. 1 shows Multi-Stage Split Case Turbine Pump for Medium and High Pressures. Direct Connected to electric motor.

Illustration No. 2 shows Double Suction Pump for circulating low or medium leads. Directly connected to steam turbine.



No. 2

WHEN you install an Inglis Pump you may feel certain that you have made a safe choice.

Put your problems up to Inglis Engineers. Their expert advice is yours for the asking.

Write us.

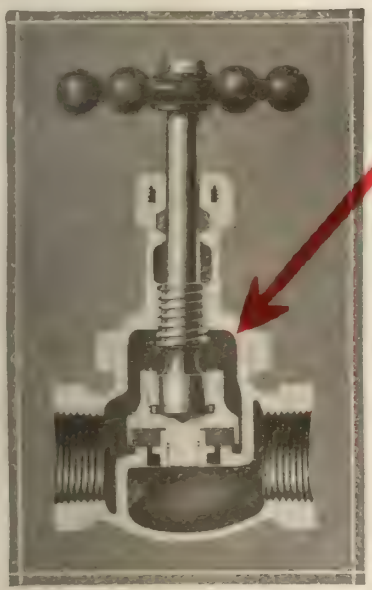
PENBERTHY

BRASS VALVES

"THE ALL QUALITY LINE"

Outside Bonnet Construction



Sectional View

The discs used in our valves do not crack or flake under high steam pressures or severe conditions. They give the best service.

They are interchangeable as regards shape, size, etc., with other standard makes of discs on the market.

If your dealer can't supply you write us.

Follow the Arrow

It takes you to the one big improvement in valve construction and found in **all** Penberthy Valves, viz., **Outside Bonnet Construction.** Do you realize what this means to you as regards your personal safety from accidents? There can be

NO SPREADING OF BONNET END

of body when screwing down bonnet tight, causing a loose-fitting and unsafe bonnet.

NO CORROSION OF THREADS

causing the bonnet to freeze to body, because the threads are outside—away from action of steam and water, etc. Therefore there is no straining of valve when taking same apart. For the same reason you can see how easy it is to take the bonnet off without strain or brute force.

This is the Name

COMPODISK

Cast on the body of every genuine Penberthy Valve of this type (with the composition disc), but if you don't insist on the genuine you are liable to get the same old model valve that has never kept up with the present progressive age. When you buy the Penberthy Valve you are going to enjoy real valve comfort. Don't be satisfied with what you have been using, but make up your mind right now to order Penberthy Valves the next time.

Penberthy Valves are made in the same shops by same workmen that make the Penberthy Injector. Doesn't that Guarantee Service and Quality?

Write for Free Valve Catalog

Penberthy Injector Co., Limited, Windsor, Ont.

Unequaled Service Through Co-operative Distribution

One of the principal objects accomplished by the new method of marketing our mechanical goods is the increased co-operation that has been made possible with dealers and jobbers.

The well-known brands of our subsidiary companies—

Revere Rubber Co.
Peerless Rubber Mfg. Co.
Mechanical Rubber Co., Cleveland.
Mechanical Rubber Co., Chicago.
Sawyer Belting Co.
India Rubber Co.
Eureka Fire Hose Mfg. Co.

are now marketed through ONE strong sales organization—
UNITED STATES RUBBER COMPANY, MECHANICAL GOODS DIVISION.

We are now able to offer dealers and jobbers a stronger and more complete line of mechanical goods than ever before offered by any rubber company.

We deeply appreciate the great service rendered by dealers and jobbers to consumers. We feel that in making it possible for consumers to purchase their favorite brands of packing, belting and hose through their own dealer and jobber, we are assisting the consumer as well as the dealer and jobber. Dealers and jobbers everywhere now have an unexampled opportunity to promote the interests of their customers as well as themselves, by taking advantage of the attractive proposition presented in the wide variety of well-known brands assembled in the United States line of mechanical rubber goods. We wish and intend to do everything to extend the numbers of dealers and jobbers, as we realize that this means greater service to consumers.

Dealers and jobbers are enthusiastically co-operating in the new plan, and as merchants they have been quick to grasp the strength of this complete line of mechanical rubber goods, embracing such famous brands as

Rainbow Packing
Honest John Packing
Peerless Spiral Packing
Rainbow Belting
Eureka Fire Hose
Giant Steam Hose
Relio Conveyor Belt
Holdtite Friction Tape
Rainbesto Packing
Buckeye Splicing Tape
Four-Ace Seamless Belting
Paragon Fire Hose
Anaconda Tender Hose
Peerless Air Hose
Kold-Pak Jar Rubbers
Revere Garden Hose
Spring Step Heels
Giant Seamless Belting
Giant Suction Hose
Usudurian Packing

all bearing, in addition to their own well-known trade-mark, the great seal signifying service and quality of the largest rubber manufacturer in the world.

It takes an expert

to plan and carry out a successful military campaign.

And it takes experts at home to keep the wheels of industry turning at their maximum speed, efficiency and economy.

In the Hoyt Metal Co.'s plant a body of picked men, headed by an expert metal mixer, work intelligently, enthusiastically, energetically, bent on turning out the best metals man can make. Under a perfect, smooth-working system entirely devoid of "red tape" they are giving manufacturing Canada the benefit of years of experience in the alloying of metals. They are putting a quality into Hoyt Metals that can be found in no other alloys.

Stopping Canada's Coal Supply!

Uncle Sam will have a fuel problem to meet again next winter. He will need every pound of coal he can muster. He will probably be forced to cut off a very considerable portion of his shipments to Canada.

This will bring Canada face to face with a very serious fuel situation—for the bulk of Canada's coal supply comes over the border.

Thus it behooves Canadians to save every ounce of coal within the range of possibilities. An invaluable opportunity to do this is presented to Canadian Power Plants by the use of the

COPPUS Turbo Blowers

Coppus Turbo Blowers will burn the poorest coal mined and will keep up steam regardless of poor fuel, poor draft, extreme weather conditions, or heavy demands upon your boilers.

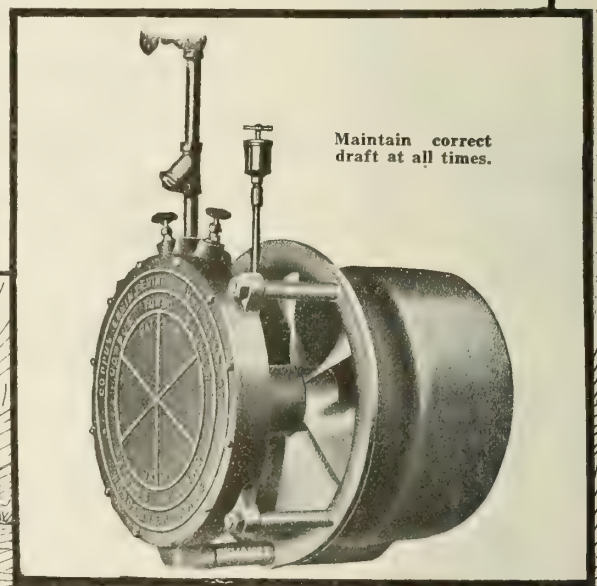
Further, Coppus Turbo Blowers will increase your present steaming capacity to 200%, and in connection with stokers even 300% of normal rating of the boilers without danger of doing injury to the boilers.

Over 1,000,000 H.P. equipped in 5 years. That's the record of Coppus Turbo Blowers. Since the fuel problem has become acute they are in demand everywhere. They are replacing other blowers, too, because of their superior efficiency. Order now and begin saving fuel without any further delay.

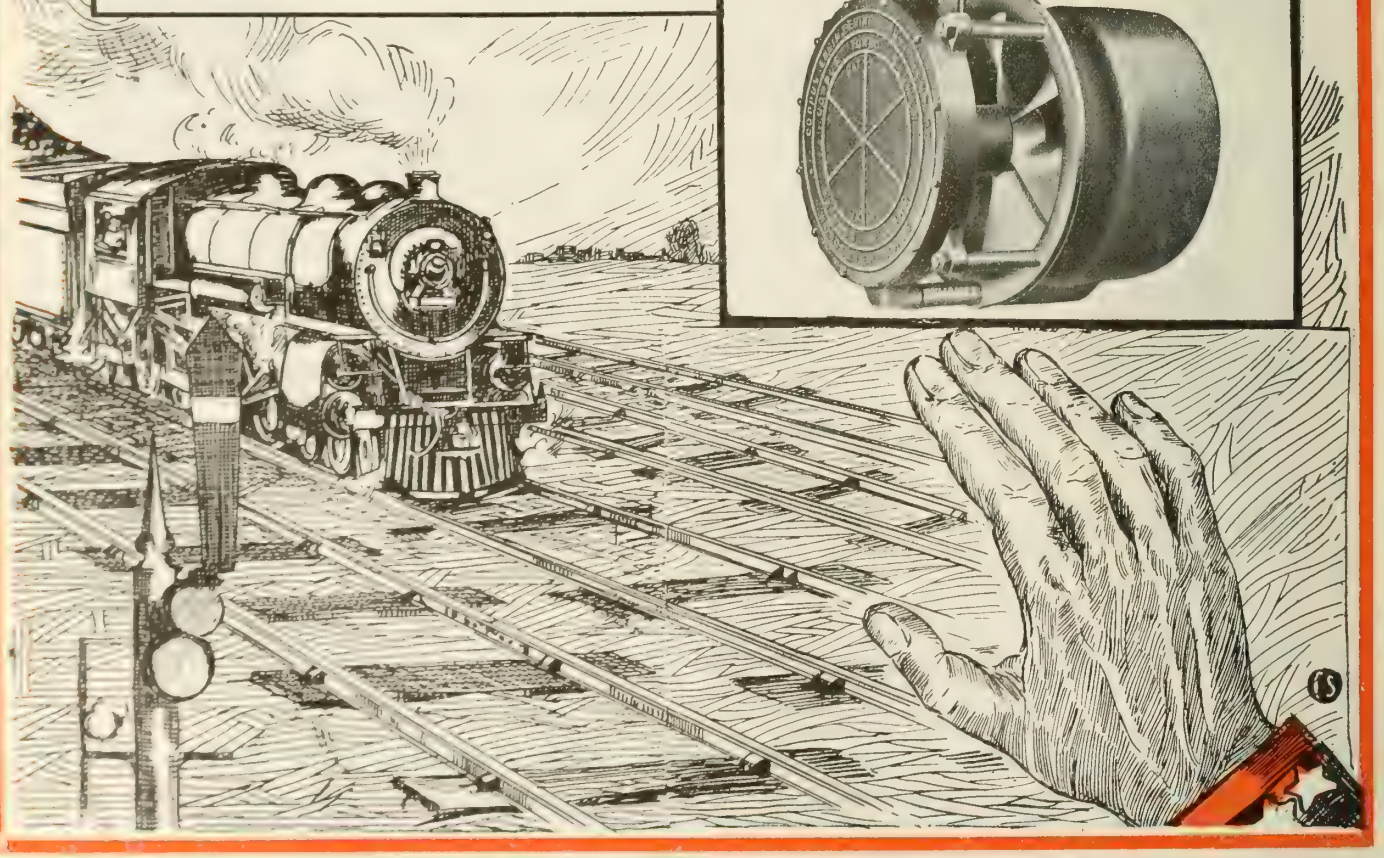
Coppus Engineering & Equipment Co.

167 Union Street, Worceste·, Mass.

CANADIAN AGENTS.—Montreal, Mason Regulator & Engineering Co., 135 Dagenais Street. Toronto, The Arthur S. Leitch Co., 506 Kent Bldg. Winnipeg, Wm. Carter, 817 Union Bank Bldg.



Maintain correct draft at all times.



Problem for Canadian Power Plants!

Present indications are that fuel shortage will constitute an exceedingly serious problem for Canadian power plants throughout the duration of the war.

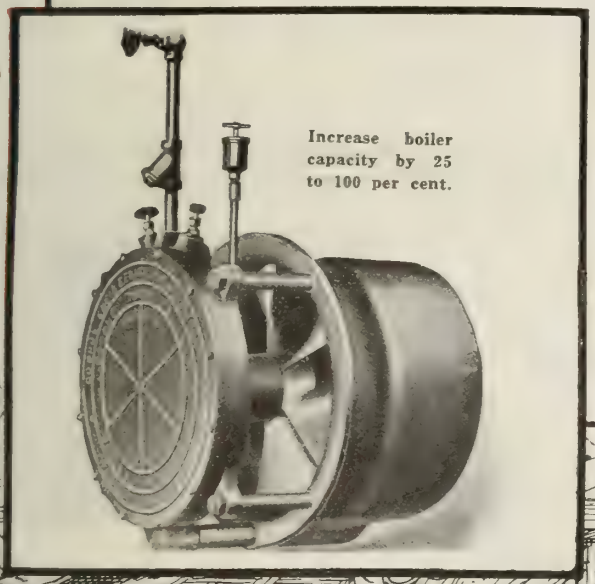
You owe it to your country and you owe it to your own business interests to give this problem your most serious attention. And the time to take action is NOW.

Back up the Fuel Controller in his efforts to ward off a crisis and at the same time save money for yourself by installing

COPPUS Turbo Blowers

Fill the Bill in an Emergency

Overseas shipping and railroads demand the best grade of bituminous coal. They must be supplied equal to their requirements. You may have to burn a low grade of coal as a consequence. But this will not cause you any concern if you have installed **Coppus Turbo Blowers.**



Increase boiler capacity by 25 to 100 per cent.

They enable power plants to make steam with anything in the form of coal—even what looks like black dirt—and at the same time greatly increase boiler capacity.

Because they make combustion conditions instantly adjustable to the coal, no matter what the grade—because the draft is always under CONSTANT CONTROL.

Scientifically correct design; simplicity, ruggedness, power and low steam consumption make COPPUS TURBO BLOWERS constant dividend payers under normal conditions as well as indispensable in emergencies.

Write us and let us show you how easily you can cope with the fuel problem which is bound to confront you for one, two or three years to come. The fact that we are equipping on an average 100,000 B.H.P. per month with Coppus Turbo Blowers is ample proof of our ability to serve you.

Coppus Engineering & Equipment Co.
167 Union Street Worcester, Mass.

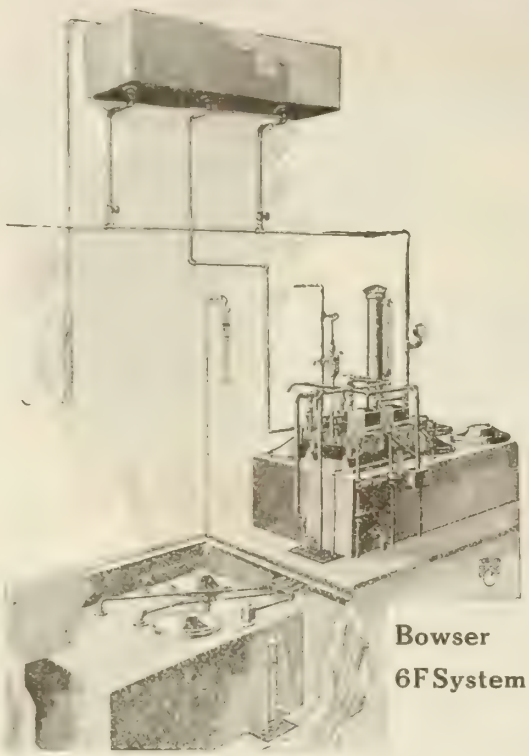
MORE POWER—LESS COST



Bowser
6F System

BOWSER
ESTABLISHED 1885

Filtration Systems enable a supply of clean, cool oil to be fed to engine bearings at all times.

Clean oil, free from dirt and grit, reduces friction, thus releasing power formerly lost. More power with the same amount of fuel and energy means less cost.

The illustration shows the Bowser 6F Filtration System. Especially suited where large quantities of water return with the dirty oil.

Write for Booklet 33.

GARLOCK PACKINGS

"SPARE THE ROD"

DUST and grit are as injurious to piston rods as inferior and poorly lubricated packing. All styles of Garlock Ring Packing are enclosed in press-board tubes and are packed in cartons that are practically dust-proof, which not only prevents accumulation of dirt and grit on the packing but likewise prevents drying out of the lubrication.

ON the blank lines of the label attached to the end of each box of Garlock Packing are entered the name of the rod for which the packing is intended and the order numbers, section number and style number of the packing, which enable a customer to reorder a box of packing without remeasuring the rod and without likelihood of making mistakes in specifications.

Our packings are billed at net weights; the weights of boxes and tubes are not included.

THE GARLOCK PACKING COMPANY

At the C.A.S.E. Convention

to be held at London, Ontario, June 25, 26 and 27th, we are showing the following lines:

Webster Sylphon Traps
Webster No. 7 Trap.
Dexter Reseating Machines.
Reliance Marine Reducing Valve.
Water Seal Trap.
Water Systems (Hydro Pneumatic).
Modulation Valves.
Pressure Reducing Valves.
Clark Flexible Coupling.
Feed Water Filters.
Pumps.

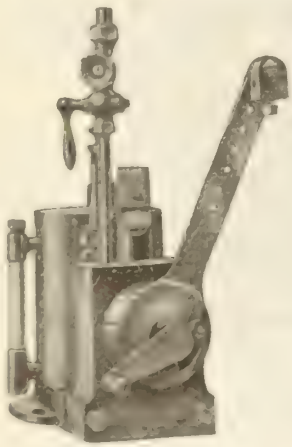
Ask to see these machines and devices, find out their good points, then you will realize why our product is so much in demand.

We are going to do **our** best to make the Convention a success. Try and do **your** best.

Darling Brothers Limited 120 Prince Street Montreal

Pumps for any Service. Webster System of Heating. Steam Appliances. Elevators.

When an Engineer says—



Clutch Drive Pattern

"I HAVE a Rochester Lubricator in my plant that has been running steadily for 12 years," you may rest assured that it will pay you to replace your old lubricator with a Rochester.

One Rochester will prove it. Give it a trial on your engine. Specify it when you buy a new engine, air compressor or pump. Remember all oil is utilized, which eliminates waste, and there is positive lubrication.

THE

ROCHESTER LUBRICATOR

JONES

Underfeed Automatic STOKERS

THERE IS NO WASTE with a Jones Underfeed Stoker in action—everything that should be burned to generate steam is consumed. An immediate and permanent result that comes from the installation is a SAVING OF FROM 15 to 25%.

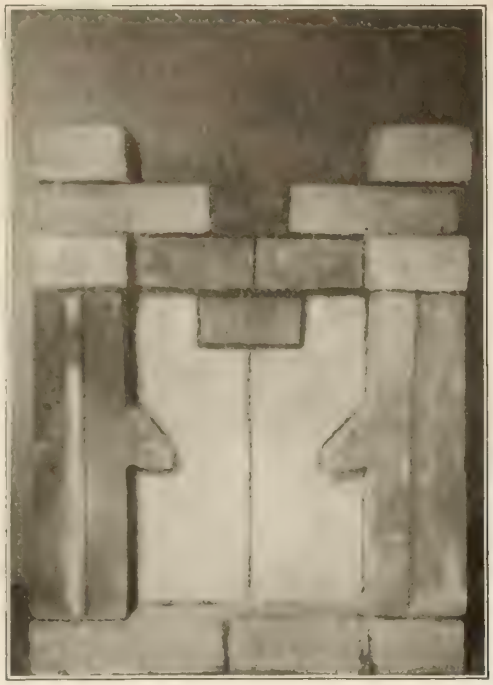
Jones Stokers maintain a constant steam pressure, due to the automatic control of air supply and coal feed, take care of large overloads—and there are many other advantages in using them.

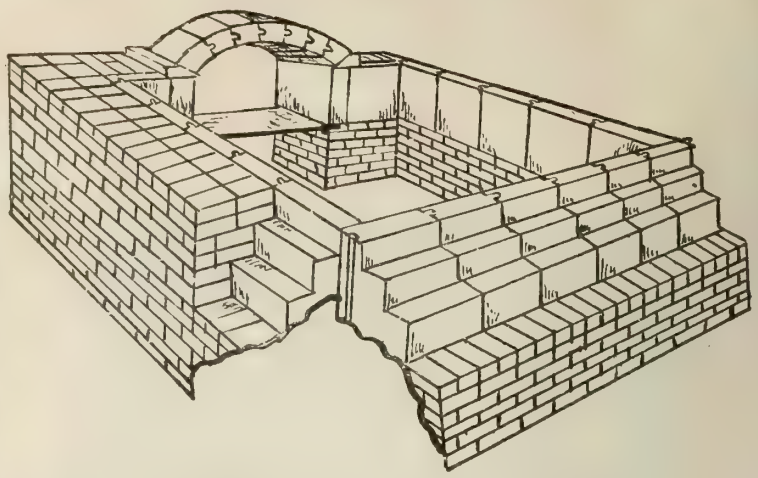
Give us your name and address and we'll gladly send you full particulars.

Jones Underfeed Stoker Co., Limited

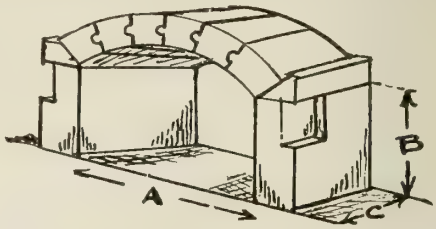
37-41 Britain St., TORONTO

Jones Underfeed Stoker Installation in the C.P.R. Passenger Terminal, Quebec





GATES BOILER FURNACE LINING (Pat. 1916)
When ordering give dimensions of Firebox and Doors



GATES BOILER DOOR ARCH AND JAMBS
When ordering give above dimensions

Gates Patent Furnace Linings are the simplest and most durable linings made. Their use materially reduces the number of joints in the furnace walls, clinkers do not readily form on their smooth and even surfaces, and the tongued and grooved joints prevent air leaks, thus the linings not only last longer, but tend to promote better combustion. The material used is very hard and refractory; the softening point is 1,700 degrees Centigrade. These qualities are essential to a good boiler setting. These furnace side wall blocks, when fused out, can be replaced without disturbing the adjoining brickwork by any handy man.

First-grade Firebrick, Fireclay, High Temperature Cements, etc., carried in stock.

Quotations given on all kinds of special shaped fireclay goods.

Write to-day for catalogue and full particulars of this lining. Information will be gladly furnished on request.

JOHN W. GATES

382 St. James St. Montreal, Que.

Are Real Coal Savers

BECAUSE:---

THEY burn cheap fuel—and less of it.

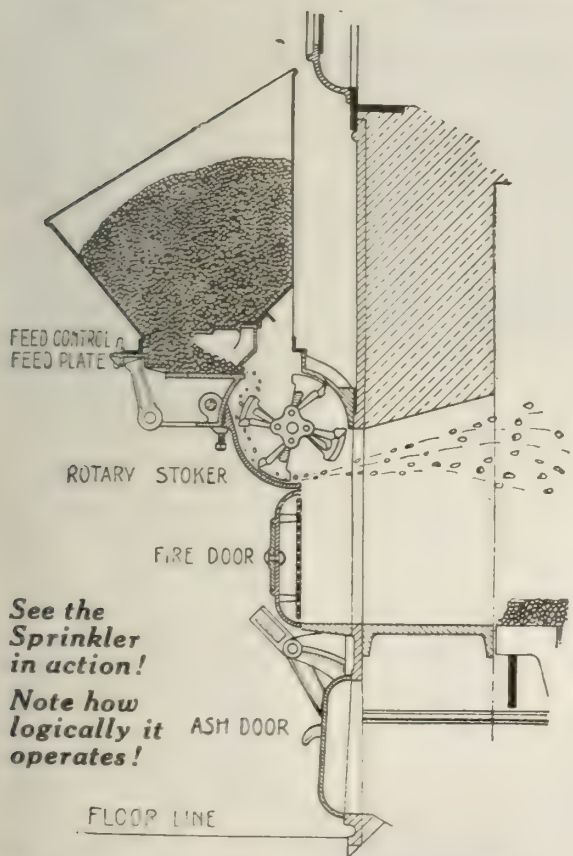
" give complete and smokeless combustion.

" feed the fuel to the furnace with the doors shut.

" do not require skilled firemen.

" maintain a brilliantly hot fire.

" are simple, strong and carefully made.



See the Sprinkler in action!

Note how logically it operates!

The Galt Sprinkler Stoker automatically feeds and uniformly spreads the fuel to the furnace in a light continuous stream and gives a perfectly level fire, 3 to 4 inches thick.

Send for one of our Combustion Engineers to look over your plant. No obligation.

Have you our Stoker Catalogue?

Galt Foundry Co., Limited - Galt, Ont.

Boiler Scale Costs More than Boico

Think of all you pay for it—Boiler scale. In the course of a year you pay tons of coal, and all the time it acts as a check to power efficiency. Like corroding rust, it slowly but nevertheless surely shortens the life of your boiler.

The cost of Boico is trivial compared with all you pay for scale. For Boico positively removes boiler scale and absolutely prevents further formation. It saves fuel, oil and packing. It will not carry over in the steam; it will not cause foaming or priming, and it is guaranteed not to injure packing or valves in the slightest. **Write for free trial.**

Anti-Clinker Shell Bar Grates

insure more heat from much less coal. Built on a scientific air-draft principle, fully 50% of the total surface air space, they provide ample air to command perfect combustion, adding as much as 25% more heat to the fuel gases and so preventing clinker formation. Moreover, Anti-Clinker Shell Bar Grates cannot twist or warp, and they're easily cleaned.

Copper Asbestos Boiler Gaskets

are made of copper, with pure asbestos cord-filled corrugations. They put a stop to leaks in pipe lines, for they never blow-out and never stick.

Tip-It Patent Welding Process

gives you tools whose shanks are carbon and whose cutting tips are high-speed steel. A money-saver!

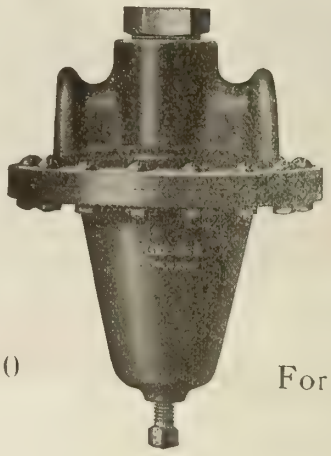
MUELLER



E5010 For Water

Reducing and Regulating Valves

Before you install your valve, be absolutely sure on these three points.

1. The right kind of valve is the one that is adapted to your particular service. No one type will answer all purposes. Different service and at times different conditions in the same kind of service necessitates different types of valves.

2. The right size of valve is the size that will make the proper reduction and regulation and has a wide enough seat opening to prevent obstruction and cutting out of the seat. *A general fault is using a valve that is too large.* Ordinarily they should be smaller than the pipe to which they are attached.

3. Proper assembling means that valves should have working parts suitable to service, and diaphragms and springs suitable to pressure range.

Don't guess. Consult us. When valves are installed under MUELLER supervision, we fully warrant them to perform the service for which we recommend them.

We make valves for water, steam, gas, air, oil and ammonia. There is a stock valve in our catalog that will meet your needs. If you have a specially intricate problem to solve, our experts are at your command.

"VULCABESTON" RED FIBRE SHEET PACKING

ENDURANCE

"VULCABESTON" RED FIBRE SHEET PACKING

The final test of the value of any packing is **endurance—how long it keeps the joint tight.**

Every blow-out, every leaky joint, means trouble and expense, and their number largely depends upon the packing you use. You can save these losses by using

VULCABESTON

Red Fibre Sheet Packing

VULCABESTON Red Fibre Sheet Packing will make joints that will last under any and all conditions: even under conditions fatal to other packings.

VULCABESTON Red Fibre Sheet Packing is not a one-track packing. It is universal in its application, and can be used with equal advantage for steam (wet, dry or superheated) water, oil, gas, ammonia—anywhere or for any service.

VULCABESTON Red Fibre Sheet Packing will stand extreme heat without baking or vulcanizing; is impervious to moisture, cuts easily and seats perfectly—and it always makes a tight joint that stays tight. We claim that for all-around service, Vulcabeston is without a peer. Try it, and find out whether we're right or not! You surely cannot afford to neglect a packing that offers the unusual advantages that Vulcabeston does.

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compressors

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction.* Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under any unforeseen strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satisfactory operation, but practically ***eliminates expensive shut-downs.*** Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring oiled bearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

JOHNS-MANVILLE SERVICE
COVERS THE CONTINENT

JOHNS-MANVILLE PACKINGS

Designed by Engineers for Engineers

THE further from the boiler your leaks occur, the more they cost you at the coal pile. Power saved in steam means more than power saved in coal.

So your rod friction in pump, compressor or engine becomes a costly loss. The same holds true of flange losses or piston leaks. All of which proves the importance of careful packing.

It is for this reason that Johns-Manville has taken the subject of packing seriously, put it on an engineering design basis and built each type to pass the most severe laboratory and service tests. It is years of this kind of work that has finally developed a standard line of packing—each one of which is backed by a logical engineering reason.

Any one packing is unique in its field—the list as a whole constitutes an important contribution to power plant economy.

"How Can I Reduce My Fuel Costs?"

UPSTAIRS the building Owner or Superintendent is asking that question as he figures up his fuel bills. With coal so high and scarce and the necessity for laying in next winter's supply staring him in the face, no wonder he's worried. He's up against it for fair.

Here's a big chance for the stationary engineer to put a smile where there's a worried look and a frown. How glad the Superintendent would be to know about The Dunham Radiator Trap — the big coal saver—The Guardian of the Coal Pile.

Many, many buildings are now being equipped with Dunham Radiator Traps. Wherever this is done a big saving in coal is effected. This is because The Dunham Radiator Trap prevents any waste of steam. Every ounce of coal—every latent bit of energy in the fuel is utilized to produce heat. No steam is lost through leaking air valves or fighting imprisoned air in the radiators.

It's up to you to cut down those fuel bills for the Superintendent. The Dunham Radiator Trap offers you this big opportunity. Go upstairs and talk to the Superintendent while he's wondering how to get more heat at less cost.

The quicker the building is equipped with Dunham Radiator Traps the sooner will the fuel bills begin to drop and a smile of satisfaction settle down on the face of the owner or manager of the building.

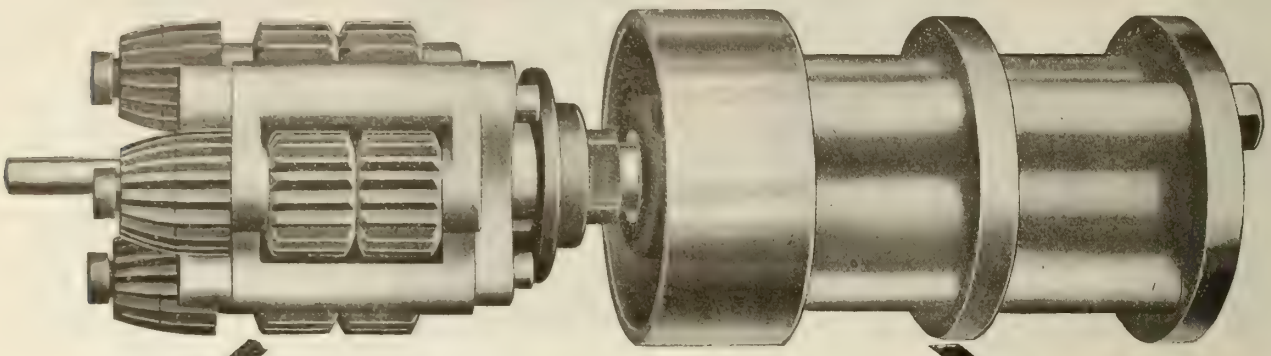
CLEAN YOUR BOILER TUBES

IN LESS TIME, WITH LESS POWER



You can remove all of the scale and keep the tube surfaces clean and polished by frequent use of

ROTO

TUBE CLEANERS

Unrivaled in speed and durability. By far the cheapest cleaners because of their high efficiency. They combine the most powerful, reliable and durable motors with the most effective scale-removing tools.

Hardened Steel Armor Rings thoroughly protect the motor. The hard steel rings keep it straight, round, up to size and a correct fit for the boiler tube even after long use. Roto motors cannot pass over scale or get wedged and stuck in the boiler tube. They positively eliminate the usual trouble of wearing oval, taper or undersize.

Roto Tube Cleaners include air, steam and water driven, cleaners for all kinds of straight and curved tubes of iron, steel, cast iron, copper, brass, etc., in boilers, fuel economizers, heaters, condensers, evaporators, etc.

HOT PROCESS WATER SOFTENER FOR STEAM BOILER PLANTS

A Cochrane Softener Installat on at a large chemical works

Economic Benefits

1. **Fuel is saved by reason of heating the boiler feed water with** exhaust steam to 210° Fahr. or higher (depending upon the back pressure carried), 1% being saved for each 11 degrees rise in temperature, that is, 10 to 15% altogether.

2. **Due to pre-heating the water, the steaming capacity of the boiler is increased** in the same proportion that fuel is saved, and by a further amout due to clean heating surfaces.

3. **Due to lessened tendency to foaming, the forcing or driving capacity of the boilers is increased.**

4. **The boilers and piping are protected against corrosion.**

5. **Tube renewals, rolling in of leaky tubes, re-calking of seams, patching of plates, etc., are eliminated or greatly reduced.**

6. **Boiler explosions due to burned or corroded plates are eliminated, and the life of the boiler is in any case greatly increased.**

7. **The cost of carrying spare boilers for use while others are being cleaned or to carry overloads** can often be avoided by maintaining all the boilers clean and ready for service.

8. **Economies result from utilizing cheap sources of water supply,** such as wells or creeks, eliminating the cost of city water or the cost of pumping water long distances.

The Sorge-Cochrane Hot Process Softener for treating boiler feed water represents a radical improvement and embodies the latest developments in the art of softening water. It differs from other systems in that the chemical reagents required for the transformation of the scale-forming and corrosive substances are added to the water while it is hot, that is, after it has been heated to boiling point by spraying through an open steam bath.

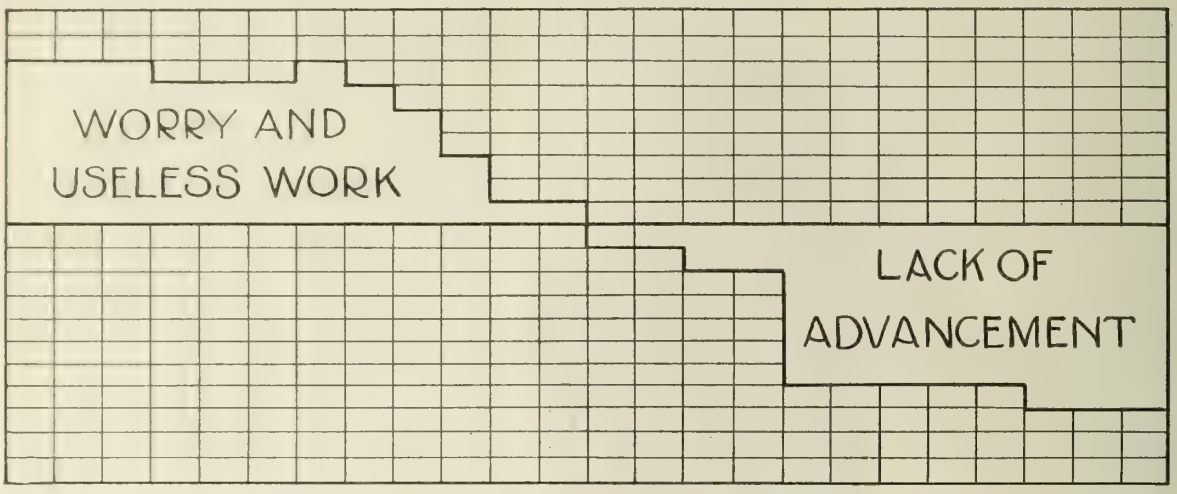
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.
